W91-01907 2H

UNIVERSITY OF THE PACIFIC, STOCKTON, CA. SCHOOL OF ENGINEERING.
Application of the HSPF Model to Water Management in Africa.
W91-01199 6B

UPPSALA UNIV. (SWEDEN). DEPT. OF ZOOLOGY.
Influence of Cadmium and Zinc on Cadmium Turnover in the Zebrafish, Brachydanio rerio.
W91-01310 5C

UPPSALA UNIV. (SWEDEN). LIMNOLOGISKA INSTITUTIONEN.
Occurrence of Limnic Micro-Crustaceans in Relation to pH and Humic Content in Swedish Water Bodies.
W91-01350 2H

Selenium as a Nutrient for Freshwater Bacterioplankton and Its Interactions with Phosphorus.
W91-01802 2H

UTAH STATE UNIV., LOGAN. DEPT. OF AGRICULTURAL AND IRRIGATION ENGINEERING.
Reconnaissance-Level Alternative Optimal Ground-Water Use Strategies.
W91-01557 6D

UTRECHT RIJKSUNIVERSITEIT (NETHERLANDS). DEPT. OF PLANT ECOLOGY.
Relations Between Acid Rain and Vesicular-Arbuscular Mycorrhiza.
W91-01410 5C

VANDERBILT UNIV., NASHVILLE, TN. DEPT. OF CHEMISTRY.
Soil Clean Up by In-situ Aeration: V. Vapor Stripping from Fractured Bedrock.
W91-01756 5G

VANDKVALITETSINSTITUTET, HOERSHOLM (DENMARK).
Advances in Estimating Bacterial Biomass and Growth in Aquatic Systems.
W91-01334 5A

Incorporation of Thymidine, Adenine and Leucine into Natural Bacterial Assemblages.
W91-01931 2L

Expression of Results from Growth Inhibition Toxicity Tests with Algae.
W91-02031 5C

VENICE UNIV. (ITALY). DEPT. OF ENVIRONMENTAL SCIENCE.
Time Trend of PCB Concentrations in Surface Sediments from a Hypertrophic, Macroalgae Populated Area of the Lagoon of Venice.
W91-01448 5B

Persistent Metabolites of Alkylphenol Polyethoxylates in the Marine Environment.
W91-01754 5B

VETERANS ADMINISTRATION MEDICAL CENTER, PITTSBURGH, PA. SPECIAL PATHOGENS SECTION.
Failure of a Diagnostic Monoclonal Immunofluorescent Reagent to Detect Legionella pneumophila in Environmental Samples.
W91-01764 5A

VICTORIA UNIV. OF MANCHESTER (ENGLAND). DEPT. OF ENVIRONMENTAL BIOLOGY.
Design for an Occult Precipitation Collector.
W91-01291 7B

VICTORIA UNIV. OF MANCHESTER (ENGLAND). DEPT. OF GEOGRAPHY.
Minimum Froude Number and the Equilibrium of Alluvial Sand Rivers.
W91-01874 2E

VICTORIA UNIV., WELLINGTON (NEW ZEALAND).
Environmentalism, Policy Factors and the Courts in New Zealand.
W91-01622 6E

VIENNA UNIV. (AUSTRIA). INST. FUER METEOROLOGIE UND GEOPHYSIK.
New Equation for the Atmospheric Energy Budget (Eine Neue Gleichung fuer die Atmosphaerischen Energiehaushaelte).
W91-01581 2B

VIENNA UNIV. (AUSTRIA). INST. FUER METEOROLOGIE UND GEOPHYSIK.

Changeable Weather-A Chaotic Phenomenon Triggered off by Mesoscale Precipitation-Eddies (Wetterlaunen als Chaotische Meso-Skalige Strukturen).
W91-01582 2B

VIRGINIA INST. OF MARINE SCIENCE, GLOUCESTER POINT.

Nutrient Exchanges Betwecn the Water Column and a Subtidal Benthic Microalgal Community.
W91-01897 2H

VIRGINIA INST. OF MARINE SCIENCE, GLOUCESTER POINT. DEPT. OF BIOLOGICAL AND FISHERIES SCIENCES.

Effects of Sunlight and Autochthonous Microbiota on Escherichia coli Survival in an Estuarine Environment.
W91-01663 5B

VIRGINIA POLYTECHNIC INST. AND STATE UNIV., BLACKSBURG. CENTER FOR ENVIRONMENTAL AND HAZARDOUS MATERIAL STUDIES.

Relation Between Saturated Conductivity and Capillary Retention Characteristics.
W91-01303 2F

Macroinvertebrate Community Responses to Copper in Laboratory and Field Experimental Streams.
W91-01312 5C

VIRGINIA POLYTECHNIC INST. AND STATE UNIV., BLACKSBURG. DEPT. OF BIOLOGY.

Changes in Stream Morphology and Storm Transport of Seston Following Watershed Disturbance.
W91-01505 2J

VIRGINIA UNIV., CHARLOTTESVILLE. DEPT. OF ENVIRONMENTAL SCIENCES.

Theoretical Model of Optimal Drainage Networks.
W91-01526 2E

VRIJE UNIV., AMSTERDAM (NETHERLANDS). BIOLOGICAL LAB.

Spirogyra Species and Accompanying Algae from Pools and Ditches in The Netherlands.
W91-01333 5C

VRIJE UNIV., AMSTERDAM (NETHERLANDS). DEPT. OF PHARMACOCHEMISTRY.

Comparative Toxicokinetics of 2,2'-Dichlorobiphenyls and 4,4'-Dichlorobiphenyls in the Pond Snail Lymnaea stagnalis.
W91-02036 5C

VYZKUMNY USTAV VODOHOSPODARSKY, PRAGUE (CZECHOSLOVAKIA).

Reaction of Microbial Periphyton to Substrate Concentration Changes in a Running Water Model.
W91-01603 2H

Numbers and Activity of Bacterioplankton in Various Types of Waters in Czechoslovakia: Relations to Chlorophyll Concentration.
W91-01610 2H

WARSAW UNIV. (POLAND). DEPT. OF CHEMISTRY.

Trends in the Heavy Metal Levels in the Dissolved and Particulate Phase in the Dutch Rhine-Meuse (Maas) Delta.
W91-01817 5B

WARSAW UNIV. (POLAND). DEPT. OF ENVIRONMENTAL MICROBIOLOGY.

Production and Utilization of Organic Matter by Microplankton in an Eutrophic Lake.
W91-01594 2H

Substrate-Ectoenzyme Interaction: Significance of beta-Glucosidase Activity for Glucose Metabolism by Aquatic Bacteria.
W91-01597 2H

Application of the Isotope Dilution Principle to the Determination of Substrate Incorporation by Aquatic Bacteria.
W91-01599 2H

WASHINGTON STATE UNIV., PULLMAN. COLL. OF PHARMACY.

Effect of Body Size on the Uptake and Bioconcentration of Di-2-Ethylhexyl Phthalate in Rainbow Trout.
W91-01257 5B

Effect of pH on the Accumulation Kinetics of Pentachlorophenol in Goldfish.
W91-01321 5B

WASHINGTON STATE UNIV., PULLMAN. LAB. FOR ATMOSPHERIC RESEARCH.

Hailstones as Cloud Water Composition Probes: An Initial Assessment.
W91-01289 2K

WASHINGTON UNIV., SEATTLE. COLL. OF OCEAN AND FISHERY SCIENCES.

Contribution of Organic Acids to Alkalinity in Lakes Within the Mount St. Helens Blast Zone.
W91-01051 2H

WASHINGTON UNIV., SEATTLE. DEPT. OF GEOLOGICAL SCIENCES.

Influence of Debris Flows on Channels and Valley Floors in the Oregon Coast Range, U.S.A.
W91-01882 2J

WASHINGTON UNIV., SEATTLE. INST. FOR MARINE STUDIES.

Response of Coastal Zone Management Programs to Sea Level Rise in the United States.
W91-01619 6B

WASHINGTON UNIV., SEATTLE. SCHOOL OF OCEANOGRAPHY.

Biogeochemistry of Carbon in the Amazon River.
W91-01039 5B

WATER RESEARCH CENTRE, MEDMENHAM (ENGLAND). MEDMENHAM LAB.

Examination of the Range of Copper Complexing Ligands in Natural Waters Using a Combination of Cathodic Stripping Voltammetry and Computer Simulation.
W91-01715 5B

WATER RESEARCH CENTRE, SWINDON (ENGLAND). ASSET MANAGEMENT.

Role of Asset Management.
W91-01272 6A

WATER RESEARCH COMMISSION, PRETORIA (SOUTH AFRICA).

Treatment of Eutrophic Waters in South Africa.
W91-01074 5F

WATERLOO UNIV. (ONTARIO). DEPT. OF EARTH SCIENCES.

Device for In Situ Determination of Geochemical Transport Parameters. 1. Retardation.
W91-01293 5B

WATERLOO UNIV. (ONTARIO). DEPT. OF GEOGRAPHY.

Estimate of Snow Avalanche Debris Transport, Kaghan Valley, Himalaya, Pakistan.
W91-01371 2J

WATERLOO UNIV. (ONTARIO). INST. FOR GROUND WATER RESEARCH.

Chlorinated Solvents in UK Aquifers.
W91-01271 5B

WATERWORKS OF NORTH-HOLLAND, BLOEMENDAAL (NETHERLANDS).

Deep-Well in the North-Holland Dune Area.
W91-01304 4B

WATSON HAWKSLEY, HIGH WYCOMBE (ENGLAND).

Industrial Effluents: Minimizing Environmental Impact.
W91-01246 5D

WAYNE STATE UNIV., DETROIT, MI. DEPT. OF BIOLOGICAL SCIENCES.

Benthic Macrophyte Community Core Sampler.
W91-01747 7B

WEIZMANN INST. OF SCIENCE, REHOVOTH (ISRAEL).

Dual Water Flow Pattern in the Unsaturated Zone under a Gypsum-amended Soil.
W91-01475 2G

WEIZMANN INST. OF SCIENCE, REHOVOTH (ISRAEL). DEPT. OF ISOTOPE RESEARCH.

Standing-Water Deposits as Indicators of Lat Quaternary Dune Migration in the Northwest ern Negev, Israel.
W91-01695 2

Source of Ground Water in the Deserts c Northern Chile: Evidence of Deep Circulatio of Ground Water from the Andes.
W91-01779 2

WELSH WATER AUTHORITY, BRIDGEND.

Incidence of Enteroviruses Around the Wels Coast: A Three Year Intensive Survey.
W91-01236 5

WESSEX SCIENTIFIC SERVICES, BRISTOL (ENGLAND).TECHNICAL SERVICES.

Disinfection and Screening of Sewage to Ir prove the Quality of Bathing Water at a U.I Seaside Resort.
W91-01233 5

WEST VIRGINIA UNIV., MORGANTOWN. DIV. OF PLANT AND SOIL SCIENCES.

Improved Detection of Acid Mine Wat Stressed Coliform Bacteria on Media Containi Catalase and Sodium Pyruvate.
W91-01770 5

WESTERN MICHIGAN UNIV., KALAMAZO CENTER FOR WATER RESEARCH.

pH and Redox Buffering Mechanisms in a G cial Drift Aquifer Contaminated by Land Leachate.
W91-01300

WESTINGHOUSE ENVIRONMENTAL AND GEOTECHNICAL SERVICES, CARY, NC.

Predicting Well Drawdown During Prolong Pumping.
W91-01682

WESTON (ROY F.), INC., VALHALLA, NY.

Influence of Ozonated Natural Organic Ma on the Biodegradation of a Micropollutant i GAC Bed.
W91-01753

WILFRID LAURIER UNIV., WATERLOO (ONTARIO). DEPT. OF BIOLOGY.

Effect of Air Temperature on Growth of La mouth Bass in North America.
W91-01396 4

WIMPOL LTD., SWINDON (ENGLAND).

Ecological Monitoring: The Need for a St ard.
W91-01216 3

WISCONSIN UNIV.-MADISON. CENTER FOR CLIMATIC RESEARCH.
Modified Koeppen Classification Applied to Model Simulations of Glacial and Interglacial Climates.
W91-01091 2B

WISCONSIN UNIV.-MADISON. CENTER FOR LIMNOLOGY.
Seasonal Patterns of Grazing and Nutrient Limitation of Phytoplankton in a Eutrophic Lake.
W91-01144 2H

Potential Changes in the Thermal Habitat of Great Lakes Fish after Global Climate Warming.
W91-01394 2B

Potential Effects of Global Climate Warming on the Growth and Prey Consumption of Great Lakes Fish.
W91-01395 2B

WISCONSIN UNIV., MADISON. DEPT. OF CIVIL AND ENVIRONMENTAL ENGINEERING.
Momentary Instability of a Saturated Porous Layer with a Time-Dependent Temperature Distribution, and the Most Unstable Disturbance.
W91-01518 5B

WISCONSIN UNIV.-MADISON. DEPT. OF GEOLOGY AND GEOPHYSICS.
Spatial and Temporal Patterns in the Hydrogeochemistry of a Poor Fen in Northern Wisconsin.
W91-01720 2H

WISCONSIN UNIV.-MADISON. DEPT. OF METEOROLOGY.
Decadal-Scale Changes of the Circulation in the Tropical Atlantic Sector Associated with Sahel Drought.
W91-01465 2B

WISCONSIN UNIV.-MADISON. WATER CHEMISTRY PROGRAM.
Fluxes and Transformation of Aquatic Pigments in Lake Mendota, Wisconsin.
W91-01041 2H

WISCONSIN UNIV.-SUPERIOR. CENTER FOR LAKE SUPERIOR ENVIRONMENTAL STUDIES.
Comparative Toxicities of Selected Industrial Chemicals to Microorganisms and Other Aquatic Organisms.
W91-02041 5C

WOODWARD-CLYDE CONSULTANTS, OAKLAND, CA.
PC-SYNOP, A Rainfall Analysis Tool.
W91-01204 7C

Evaluating Ground-Water Vulnerability to Pesticides.
W91-01558 5B

U. S. Federal Highway Administration's Receiving Water Impact Methodology.
W91-02000 5G

WORLD METEOROLOGICAL ORGANIZATION, GENEVA (SWITZERLAND). DEPT. OF HYDROLOGY AND WATER RESOURCES.
Supporting World Hydrology: Activities of International Hydrological Programs.
W91-01457 6E

WRC ENGINEERING, SWINDON (ENGLAND).
Odour Control for the 1990s--Hit or Miss.
W91-01275 5D

WRIGHT STATE UNIV., DAYTON, OH. DEPT. OF BIOLOGICAL SCIENCES.
Effect of Sediment Spatial Variance and Collection Method on Cladoceran Toxicity and Indigenous Microbial Activity Determinations.
W91-01262 5A

WRIGHT WATER ENGINEERS, INC., DENVER, CO.
Urban Runoff Modeling for Administrative Purposes.
W91-01193 4C

Gulf Coast Flood Routing.
W91-01210 2E

WYE COLL., ASHFORD (ENGLAND). DEPT. OF AGRICULTURE, HORTICULTURE AND THE ENVIRONMENT.
Modelling Soil Water Supply to Crops.
W91-01869 2G

WYOMING COOPERATIVE FISHERY AND WILDLIFE RESEARCH UNIT, LARAMIE.
Relations Between Brook Trout Standing Stocks and Habitat Features in Beaver Ponds in Southeastern Wyoming.
W91-01387 8I

Redd Site Selection by Brown Trout in Douglas Creek, Wyoming.
W91-01745 8I

WYOMING UNIV., LARAMIE. DEPT. OF ZOOLOGY AND PHYSIOLOGY.
Anomalous Temperature and Oxygen Gradients Under the Ice of a High-Plains Lake in Wyoming.
W91-01148 2H

WYZSZA SZKOLA INZYNIERSKA, ZIELONA GORA (POLAND).
Toxicity of Water Extracts of Hazardous Waste.
W91-01231 5C

YORK UNIV., TORONTO (ONTARIO). DEPT. OF BIOLOGY.
Size-Dependent Winter Mortality of Young-of-the-Year White Perch: Climate Warming and Invasion of the Laurentian Great Lakes.
W91-01399 8I

ZENTRALANSTALT FUER METEOROLOGIE UND GEODYNAMIK, VIENNA (AUSTRIA).
Experience with Precipitation Forecasting for the Winter Road Service (Erfahrungen mit Niederschlagsprognosen fuer den Srassenwinterdienst).
W91-01579 2C

New Snow in the Urban Area of Vienna (Neuschnee im Raum Wien).
W91-01584 2B

ZURICH UNIV., KILCHBERG (SWIZERLAND). HYDROBIOLOGICAL-LIMNOLOGICAL STATION.
Algae, Other Than Diatoms, Affecting the Density, Species Richness and Diversity of Diatom Communities in Rivers.
W91-01765 2H

ACCESSION NUMBER INDEX

SELECTED WATER RESOURCES ABSTRACTS

VOLUME 24, NUMBER 3
MARCH 1991

1-02044 -- W91-02958
DEN: SWRABW

SELECTED WATER RESOURCES ABSTRACTS (SWRA) is produced by the Geological Survey, U.S. Department of the Interior, and published monthly by the National Technical Information Service (NTIS), U.S. Department of Commerce.

SWRA is available to Federal agencies and their contractors or grantees in water resources research upon request, citing contract or grant number and sponsoring agency. Write: Water Resources Division, U.S. Geological Survey, MS 425, Reston, VA 22092. The **SWRA JOURNAL** is also available on subscription from NTIS, 5285 Port Royal Road, Springfield, VA 22161. Annual subscription rates for the North American Continent are: Journal only, $170.00, Journal and Annual Indexes, $200.00; Indexes only, $80.00. Other Addresses, write for prices.

Some documents abstracted in this journal can be purchased from NTIS. Price codes are given in the entries and a current code-price conversion table is printed on the outside back cover. Other documents are available from originating organizations or authors as indicated in the citation.

SELECTED WATER RESOURCES ABSTRACTS

A monthly publication of the Geological Survey
U.S. Department of the Interior

VOLUME 24, NUMBER 3
MARCH 1991

W90-02044 -- W90-02958

The Secretary of the Interior has deterimined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Office of Management and Budget through September 1991.

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

PREFACE

Selected Water Resources Abstracts, a monthly journal, includes abstracts of current and earlier pertinent monographs, journal articles, reports, and other publication formats. These documents cover water resources as treated in the life, physical, and social sciences and the related engineering and legal aspects of the characteristics, supply condition, conservation, control, use, or management of water resources. Each abstract includes a full bibliographic citation and a set of descriptors which are listed in the **Water Resources Thesaurus.** The abstract entries are classified into 10 fields and 60 groups similar to the water resources research categories established by the Committee on Water Resources Research of the then Federal Council for Science and Technology.

Selected Water Resources Abstracts is designed to serve the scientific and technical information needs of scientists, engineers, and managers as one of several services of the Water Resources Scientific Information Center. The cumulative SWRA file from 1968 and monthly updates are available also in magnetic tape through lease from NTIS.

THE WATER RESOURCES SCIENTIFIC INFORMATION CENTER DOES NOT PROVIDE COPIES OF DOCUMENTS ABSTRACTED IN THIS JOURNAL. Sufficient bibliographic information is given to enable readers to order the desired documents from local libraries or other sources.

Comments and suggestions concerning the contents and arrangement of this bulletin are welcome.

CONTENTS

SUBJECT FIELDS AND GROUPS

Please use the edge index on the back cover to locate Subject Fields and Indexes.

01 NATURE OF WATER

Includes the following Groups: Properties; Aqueous Solutions and Suspensions.

02 WATER CYCLE

Includes the following Groups: General; Precipitation; Snow, Ice, and Frost; Evaporation and Transpiration; Streamflow and Runoff; Groundwater; Water in Soils; Lakes; Water in Plants; Erosion and Sedimentation; Chemical Processes; Estuaries.

03 WATER SUPPLY AUGMENTATION AND CONSERVATION

Includes the following Groups: Saline Water Conversion; Water Yield Improvement; Use of Water of Impaired Quality; Conservation in Domestic and Municipal Use; Conservation in Industry; Conservation in Agriculture.

04 WATER QUANTITY MANAGEMENT AND CONTROL

Includes the following Groups: Control of Water on the Surface; Groundwater Management; Effects on Water of Man's Nonwater Activities; Watershed Protection.

05 WATER QUALITY MANAGEMENT AND PROTECTION

Includes the following Groups: Identification of Pollutants; Sources of Pollution; Effects of Pollution; Waste Treatment Processes; Ultimate Disposal of Wastes; Water Treatment and Quality Alteration; Water Quality Control.

06 WATER RESOURCES PLANNING

Includes the following Groups: Techniques of Planning; Evaluation Process; Cost Allocation, Cost Sharing, Pricing/Repayment; Water Demand; Water Law and Institutions; Nonstructural Alternatives; Ecologic Impact of Water Development.

07 RESOURCES DATA

Includes the following Groups: Network Design; Data Acquisition; Evaluation, Processing and Publication.

08 ENGINEERING WORKS

Includes the following Groups: Structures; Hydraulics; Hydraulic Machinery; Soil Mechanics; Rock Mechanics and Geology; Concrete; Materials; Rapid Excavation; Fisheries Engineering.

09 MANPOWER, GRANTS, AND FACILITIES

Includes the following Groups: Education—Extramural; Education—In-House; Research Facilities; Grants, Contracts, and Research Act Allotments.

10 SCIENTIFIC AND TECHNICAL INFORMATION

Includes the following Groups: Acquisition and Processing; Reference and Retrieval; Secondary Publication and Distribution; Specialized Information Center Services; Translations; Preparation of Reviews.

STATE-OF-THE-ART OF HYDROLOGY AND HYDROGEOLOGY IN THE ARID AND SEMI-ARID AREAS OF AFRICA.
Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. 990p. Edited by Misganaw Demissie and Glenn E. Stout.

Descriptors: *Africa, *Arid lands, *Arid-zone hydrology, *Geohydrology, *Hydrology, *Sahel, *Semiarid lands, *Symposium, Developing countries, Drought, Floods, Sudan, Water resources development, Water resources management.

The Sudan-Sahel is the southern expanse of the desert in West Africa that for many centuries has been subject to frequent droughts and flash floods. The situation is little changed today. The countries of Sudan-Sahel continue to try to juggle a precarious supply of water for municipal, industrial, and agricultural uses with their rapidly expanding populations. A significant barrier to water supply planning in this part of Africa is the lack of basic hydrological information. This volume includes presentations from a seminar held in Burkina Faso from 18-23 February 1989. The purpose of the seminar was to assemble knowledge on hydrogeology and hydrogeology in the arid and semiarid areas of Africa and make it available to the countries in this region as they seek long-range solutions to their water management questions. The more than 81 presentations cover various aspects of hydrology, hydrogeology, and water engineering appropriate to these regions, including: general and theoretical hydrology of the area; regional surface water hydrology; soils and runoff; drought and climatic factors in regional hydrology; information systems and computer applications suitable for water resources management in the Sahel; mathematical modeling; irrigation; aquifer characteristics; natural recharge of aquifers; village water supply systems; water exploration methods and instrumentation; groundwater resources; effects of pollution on aquifers and surface water quality; control of water-borne disease; hydrologic education programs; and agricultural water management. (See W91-02289 thru W91-02369) (Rochester-PTT)

DEVELOPMENT OF THEORETICAL HYDROLOGY IN WEST AFRICA (DEVELOPPEMENT DE L'HYDROLOGIE THEORIQUE EN AFRIQUE DE L'OUEST).
Universite Nationale du Benin, Cotonou. Dept. de Mathematiques.
A. Abel.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 1-14, 1 fig, 2 tab, 15 ref. English summary.

Descriptors: *Drought, *Model studies, *Rainfall-runoff relationships, *West Africa, Climates, Mathematical models, Theory.

Theoretical hydrology as it applies to West Africa is analyzed with respect to persistent droughts and rainfall-runoff relationships. Several features are required for proper understanding of hydrologic phenomena, including: continuously operated observation networks, thoroughly controlled basic data, and mathematical models incorporating dynamics, stochastic features, and non-linearity of the natural environment. The development of theoretical models associating direct observations and model concepts can be done within an appropriate working group. Validation of existing observational records and improvement of the acquisition of new data are important. The value of the interaction between theoretical and practical hydrology must be recognized to obtain a complete understanding of the hydrology of West Africa. (See also W91-02288) (Rochester-PTT)
W91-02289

HYDROLOGICAL MODELLING FOR WATER MANAGEMENT IN ARID AND SEMI-ARID AREAS OF AFRICA.
Institute of Hydrology, Wallingford (England).
R. J. Moore.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 35-46, 5 fig, 1 tab, 13 fig.

Descriptors: *Arid lands, *Model studies, *Rainfall-runoff relationships, *Semiarid lands, Decision making, Evaporation, Hydrologic models, Infiltration, Mathematical models, Vegetation, Water resources management.

Rainfall, evaporation, and runoff formation processes operating in arid and semi-arid areas differ from those in humid temperate regions. The special nature of hydrological processes in arid and semi-arid areas are reviewed in relation to the structure, data requirements, and accuracy of hydrological models for water management in such areas. Evaporation in the arid zone, rainfall in the arid zone, hydrologic models and rainfall variability, a conceptual rainfall-runoff model for semi-arid basins, drought management and decision support systems are considered. Recommendations for direction of future efforts in hydrological modeling of surface water resources in the arid and semi-arid areas of Africa are as follows: (1) further research on evaporation estimation in drylands that incorporates water use-vegetation growth models; (2) evaluation of the combined use of radar, satellite, and gauge measurements of rainfall; (3) rainfall-runoff models that explicitly account for spatially varying rainfall, even in a probabilistic way; (4) a field experiment to examine transmission losses in detail, using infiltrometers located along a wadi bed, to provide information to support predictive modeling of basin runoff; (5) give more attention to the decision making framework within which models are used and to the choice of an appropriate model prescription; (6) development of decision support systems for water resource management in semi-arid areas; and (7) seeking opportunities for demand management of water resource systems to sustain essential water supplies throughout a drought. CIEH'S CONTRIBUTION TO THE DEVELOPMENT OF HYDROLOGY IN ARID AND SEMI-ARID AREAS IN AFRICA (CONTRIBUTION DU CIEH AU DEVELOPPEMENT DE L'HYDROLOGIE DANS LES ZONES ARIDES ET SEMI-ARIDES D'AFRIQUE).
Comite Interafricain d'Etudes Hydrauliques, Ouagadougou (Burkina Faso). Dept. of Hydrology.
J. P. Triboulet.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 47-67, 12 fig, 29 ref. English summary.

Descriptors: *Africa, *Arid lands, *Data collections, *Hydrologic data collections, *Information systems, *Inter-African Committee for Hydraulic Studies, *Semiarid lands, Developing countries, Floods, Frequency analysis, Hydrologic models, Publications, Storms, Urban hydrology, Water resources development.

For about 30 yr, the Inter-African Committee for Hydraulic Studies (CIEH) has provided important leadership in hydrology of West and Central Africa. The main objective has been making available climatological and hydrological data for engineers of water resources projects. Computerized files of daily rainfall for all 13 member countries have been prepared from the origin of the stations until 1965. Extension of these files to 1980 is under way. Regional frequency analysis of the annual maximum daily rainfall has been carried. Maps showing 10-yr and 100-yr daily precipitation values are available. Monthly evapotranspiration values, calculated by Turc formula and mapped, were published in 1972. Other studies have been carried out on artificial precipitation, reduction of water losses by evaporation, and drought persistence in West Africa. CIEH has supported some national hydrological services in the development of data bank software for use on a microcomputer. CIEH has published hydrological monographs on large river basins prepared by ORSTOM. In hydrology, the main activity has been the development of methodology for studying exceptional floods and annual runoff in small rural catchments. The information collected by ORSTOM on representative catchments was used to draw deterministic relationships between flow (10-yr peak flow and annual flow) and storm event characteristics, geomorphology, and infiltration capacity of the catchment area. Another method based on a statistical approach was developed in 1983. A large program in urban hydrology began in 1976 with measurements on 25 catchment areas in 6 main cities of West Africa. These results will permit the design of a rainfall-runoff model adapted to urbanized areas. CIEH also is involved in training engineers and technicians concerned with water resources assessment and management in rural and urban areas. The Information and Documentation Center of CIEH collects specialized references in

water resources and provides support for bibliography. (See also W91-02288) (Author's abstract)

CONTRIBUTION OF CIEH IN THE FIELD OF HYDROGEOLOGY (CONTRIBUTION DU CIEH DANS LE SECTEUR DE L'HYDROLOGIE).
Comite Interafricain d'Etudes Hydrauliques, Ouagadougou (Burkina Faso). Dept. of Hydrology.
C. Di Luca.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 90-115, 1 fig, 6 tab. English summary.

Descriptors: *Africa, *Geohydrology, *Inter-African Committee for Hydraulic Studies, *Mapping, *Water resources management, Aquifers, Developing countries, Recharge, Sampling, Wells.

Since its inception CIEH (le Comite Interafricain d'Etudes Hydrauliques or Inter-African Committee for Hydraulic Studies) has had an important role in hydrogeology. A series of maps for water resources management was drawn for the 13 countries of CIEH during the period 1976-1982. These maps synthesize all acquired knowledge and give the national authorities valuable information on exploitable storages and water quality to support development projects. Development of computer-assisted cartography using the data bases already available in the member states demonstrated the advantages of evolutionary mapping. With the development of air-hammer drilling, CIEH directed an important part of its activity to understanding the water resources in crystalline bedrock and to the methodology of borehole location in these formations. Several areas are appropriate targets for future efforts, including: estimation of aquifer recharge in bedrock using observation of experimental basins and isotope studies to establish mathematical models; understanding of regional faults and adjusting geophysical methods for discontinuous aquifers; improved use of radon prospecting; combatting the problems of 'sanding-up' of wells; use of computer data bases for aquifer management; and national organization of collection and processing of hydrogeological data. TOWARDS A REGIONAL WATER RESOURCE STUDY OF ARID AND SEMI-ARID AFRICA.
Institute of Hydrology, Wallingford (England).
A. Bullock, and A. Gustard.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 118-125, 5 fig, 6 ref.

Descriptors: *Africa, *Arid lands, *Discharge capacity, *Rainfall-runoff relationships, *Regional planning, *Semiarid lands, *Water resources development, Catchment areas, Estimating equations, Soils, Ungaged streams, Zimbabwe.

Regionalization techniques generally are poorly developed in the arid and semi-arid regions of Africa compared with temperate regions. This is because of the relative scarcity of hydrological records, difficulties in derivation of appropriate flow statistics, and the absence of established extrapolation procedures. An analysis of data from 49 catchments in central Zimbabwe reveals a pedological control upon the shape of standardized flow duration curves. When combined with a regional rainfall/runoff relationship for southern Africa, a provisional procedure is established for the estimation of ungauged sites of discharges with particular exceedance probabilities. Streams in moderately shallow to moderately deep soils are characterized by a sustained flow regime compared those in shallow to moderately shallow soils, which are ephemeral and experience zero flows for approximately 18-36 days per year on average. A regional rainfall/runoff relationship has been calibrated using data from 171 catchments in four southern African countries. This enables preliminary estimates of the average daily flow at ungauged sites, which may then be used to rescale the standardized flow duration curves. In combination this procedure, although provisional, could prove valuable in enabling estimates of discharges with a given exceedance probability in southern Africa. Several opportunities exist for improving and developing this procedure. (See also W91-02288) (Rochester-PTT)

Rainfall simulation experiments have been implemented in the Sahelian zone for more than 10 years is related to worsening water management problems. They have led to the assessment and comparison of the various factors influencing infiltration and runoff in this climatic zone. The prevailing role of surface features, including vegetative cover, faunal activity, surface roughness, and surface crust, was evident. The analysis of the process and the factors involved in surface crusting, coupled with the identification of peculiar microlayers, led to the definition of a morphogenetic typology of nine major types of Sahelian crusts. In addition, grass or crop cover, faunal activity, and tillage were taken into account to characterized 11 main unit surfaces. This morphological approach coupled with rainfall experiments enabled specific hydraulic parameters to be associated with each unit surface. At a higher scale level, the concept of 'surface features' was proposed. This refers to the combination of several map unit surfaces and has been used as the basis for an original mapping method. Mapping units were considered as homogeneous both in terms of dynamics and hydraulic behavior. Also, remote sensing was used satisfactorily for mapping remote watersheds. Low-frequency floods were determined with a reasonable accuracy and results could be derived to unstudied watersheds, provided remote sensing had been combined with the rainfall experiments data and a small time step modelling. WATER LOSSES IN THE NILE BASIN.
International Inst. for Hydraulic and Environmental Engineering, Delft (Netherlands).
M. M. A. Shahin.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 148-157, 3 fig, 2 tab, 11 ref.

Descriptors: *Africa, *Arid lands, *Drought, *Evapotranspiration, *Hydrologic budget, *Nile River Basin, *Water loss, Agricultural wate Egypt, Irrigation, Lakes, Storage reservoi Sudan, Swamps.

The water shortage in Africa is becoming so acu that it has begun to threaten the entire continer From an annual rainfall of about 20,000 billion m, only some 2,500 billion cu m comprise the lon term annual flow in all African rivers. Only 10 of the stream flow is used for irrigation. Slight less than half the irrigated land in Africa lies with the Nile basin. Permanent and temporary swam in Africa occupy an area estimated at 340,000 km, causing the loss of some 500 billion cu m/ more than 10% of which is lost in swamps of t Nile basin alone. The increase in number and ar of storage reservoirs in the basin is leading to t loss of substantial volumes of water each ye Irrigated agriculture cannot be expanded unl some of the water lost is saved. Proper design conservation schemes must be based on accur estimates of the losses. Water losses for the N basin are reported here for swamps and stora reservoirs. Total water losses via these two f tures are estimated at 105 billion cu m/yr, about billion of which is accounted for storage res voirs, the rest being lost by swamps and lak Adding these losses to the irrigation losses of billion cu m/yr in Egypt and the Sudan yield total of 179 billion cu m/yr, or roughly 11% of rainfall on the Nile basin. ANALYSIS OF DROUGHT IN ETHIO BASED ON NILE RIVER FLOW RECOR
Illinois State Water Survey Div., Champaign.
M. Demissie.
IN: The State-of-the-Art of Hydrology and drogeology in the Arid and Semi-Arid Area Africa. Proceedings of the Sahel Forum, Ou dougou, Burkina Faso, 18-23 February 1989. In national Water Resources Association, Urbana linois. 1990. p 158-168, 7 fig, 2 ref.

Descriptors: *Arid lands, *Drought, *Ethio *Low flow, *Nile River, Long-term studies, R flow, Time series analysis.

The drought situation in Ethiopia, which has sulted in serious famines in 1972-1973, 1982-1 and 1987-1988, has been attributed to a short-t (7-10 yr) cycle of recurring droughts. Whether is true was assessed by examining available rec of the flow of the Nile River from 1912 until 1 Examination of these records shows a much r serious and long-term trend. The Nile R records show that the most recent three drou are associated with a long-term drying period started in the mid-1960s. With the exceptio four years, the flow of the Nile has been b normal since 1965. Not only has the lowest an flow of the Nile since 1912 been recorded w this dry period, but six of the seven lowest an flows occurring since 1912 occurred since 196 quick recovery from this trend appears unli (See also W91-02288) (Author's abstract)

The Hyberbav Program is located on a small catchment in the northwest of the Ivory Coast. Fine observations have been made on a 136-ha area from 1984 to 1988 on all the parameters that may affect water balance (hydrology, climatology, soil science, hydrogeology, and botany). The 'coupled model,' developed jointly by ORSTOM and the Ecole Nationale Superieure des Mines de Paris seems to be a good tool for incorporating all these data into a model representing the superficial and internal water exchange transfers. SYSTEMS ENGINEERING APPROACH TO SOLUTIONS OF DROUGHT IN DEVELOPING COUNTRIES: THE CASE OF TANZANIA.
New Tech International Inst., Dar es Salaam (Tanzania).
A. R. Mfutakamba.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 889-901, 22 ref.

Descriptors: *Developing countries, *Drought, *Model studies, *Political aspects, *Public policy, *Systems engineering, *Tanzania, *Water supply, Economic aspects, Management planning, Nonstructural alternatives, Performance evaluation, Rural areas, Social aspects, Urban areas.

A drought model was developed and applied to Tanzania as an example of the developing world. Factors affecting millions of poor people include climate, politics, economics, and the lack of technological capabilities to offset drought effects. The model critically examines government policy, social and technological constraints in the implementation of rural water supply, sanitation, irrigation, and energy systems based on a United States Agency for International Development (USAID) study. Contrary to the study, there seems to be no contradiction between policy and program implementation. Technological constraints seem to prevail. The model proposes a systems engineering approach to analyze the shortcomings and proposes multi-disciplinary solutions to the water economy sectoral problem. The extent of commitment on the part of the government and its nationals to the rural water supply programs is assessed. Due to the global power structure, the urban water supply and sanitation systems are still more favored than those in the rural areas where the majority live. The lack of participation in the study by women missed key subjects for research work. The focus has never been on the key foreign exchange earners: the rural poor. Even the budget structure continues to favor urban areas, not only in health services, roads, housing, and education, but in water supply and sanitation. The Tanzanian study had numerous methodological shortcomings, including: too many water professionals on the study team, lack of a local economist on the team, lack of a balance between village water supply and agricultural water supply emphasis, lack of participation by the local academic community, and the lack of an overall model to guide study design and execution. Atmospheric variations, which determine both the incoming solar radiation and greenhouse effect, are key factors of climate change. A new stage of climate theory development has begun which demonstrates the need to more adequately consider land surface processes as well as the interaction between biogeochemical cycles and climate; the biosphere must be considered as a component of the 'atmosphere-hydrosphere-cryosphere-lithosphere-biosphere' climate system. Analysis of numerical modeling results of the sensitivity of atmospheric general circulation (AGC) to the parameters characterizing the land surface processes has shown that AGC is very sensitive to surface albedo and upper soil layer moisture content. Climate models should take into account the spatial extent and optical properties of snow cover, type and density of vegetation cover, and rate of soil moisture fluctuation. Evapotranspiration is one of the most important climate-forming factors. The transfer of water and energy through the underlying surface depends on the morphological features and vegetation cover physiology. The most adequate model foresees a differentiation of vegetation cover (tropical forests, mid-latitude forests, deserts, grass cover, etc.) and its interactive connection with conditions in the atmosphere and soil. Preliminary calculations show marked effects of tropical deforestation and desertification. Sea ice cover, continental snowcover, and permafrost play important roles in cryosphere component of the climate system. The key role in the formation of climate and biospheric functioning is played by the global water cycle. (Fish-PTT)

RUNOFF GENERATION IN A SANDY AREA--THE NIZZANA SANDS, WESTERN NEGEV, ISRAEL.
Hebrew Univ., Jerusalem (Israel). Inst. of Earth Sciences.
A. Yair.
Earth Surface Processes and Landforms ESPLDB, Vol. 15, No. 7, p 597-609, November 1990. 10 fig, 3 tab, 28 ref.

Descriptors: *Dunes, *Geomorphology, *Israel, *Rainfall-runoff relationships, *Sand, *Storm runoff, Playas, Rainfall.

The study of present-day geomorphic processes in the Nizzana sand field in Western Negev, Israel, is very limited. Sprinkling experiments were conducted over the lower part of vegetated and crusted linear dunes as well as over flat playa surfaces that appear in the interdune corridors. Data obtained show that these two surface units respond quickly to rainstorms. Runoff generation can be expected for any storm exceeding 2-3 mm and runoff coefficients are high. When the topsoil algal crust, I to 2 mm thick, is removed from the surface of the dune, infiltration increases drastically and eliminates any possibility of runoff generation under present-day rainfall conditions. This data may be of great help in the understanding of the geomorphology and sedimentary sequence of the corridors separating linear dunes. (Author's abstract)

DROUGHT IN FRANCE IN 1989 (LA SECHERESSE DE 1989).
Y. Merillon, and P. Chaperon.
Houille Blanche HOBLAB, Vol. 1990, No. 5, p 325-339, 1990. 10 fig, 3 tab. English summary.

Descriptors: *Drought effects, *France, *Precipitation, *Rainfall index, *Water resources, Agriculture, Rainfall distribution, Water quality, Water scarcity.

The French drought of 1989 was comparable to the great droughts of the last half century (in 1946, 1976, 1985 and 1986) which had taken place in the southwest of France. The droughts impact many economic sectors--initially agriculture and powerplants. The droughts also caused: widespread eutrophication; the dessication of numerous rivers; increased pollution effects; and a general decline in available water resources. However, the distribution of drinking water was ensured in most cases. From November 1988 to October 1989, the total precipitation which fell on France was 560 mm or 73% of normal. This value represented an average of 31 meteorological stations and is the lowest reading from the last 32 years (1957 to 1989). The precipitation by region was: north, 559 mm (85% of normal); northeast, 663 mm (86%); west, 579 mm (74%); central east, 546 mm (69%); southwest, 631 mm (73%); southeast, 384 mm (56%); and Corsica, 434 mm (67%). Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 95-104, May 1990. 3 fig, 1 tab, 16 ref.

Descriptors: *Erosion, *Rainfall intensity, *Sediment load, *Soil erosion, Iowa River, Statistical analysis, Storms, Temporal distribution.

Sediment loadings in a stream measured after an intense storm have frequently led to the conclusion that significant soil erosion is associated only with a few storms, or that they are solely a function of peak storm intensities. The issue of the nature of the relationship between stream loading and storm intensity and whether stream sediment loading can best be explained by storm intensity (rainfall) or whether a more general average rainfall measure is superior was examined. Based on data covering the years 1947 to 1985 for the Iowa River watershed north of Iowa City, a nonlinear relationship between stream sediment loading and rainfall is indicated. Moreover, average monthly rainfall better explains sediment loading than do other measures of storm (rainfall) intensity. Finally, when the structural stability of the estimated relationships between stream loading and storm intensity are estimated, the conclusion is that the relationship between stream loading and rainfall is stable over the sample period. PARAMETERIZATION OF THE ACCRETION PROCESS BETWEEN DIFFERENT PRECIPITATION ELEMENTS.
Meteorological Research Inst., Yatabe (Japan).
H. Mizuno.
Journal of the Meteorological Society of Japan JMSJAU, Vol. 68, No. 3, p 395-398, June 1990. 2 fig, 26 ref.

Descriptors: *Accretion, *Clouds, *Mathematical analysis, *Precipitation, Accretion rate, Aggregation, Atmospheric physics, Mathematical equations, Mathematical models, Parameterization, Particulate matter.

Accretion processes in simultaneous different precipitation elements with their related aggregation process play important roles in precipitation formation. These processes produce a large mass transfer between precipitation particles and a broadening of the size distribution. In prior cloud models, a detailed evaluation of the parameterization of the accretion rate has been lacking. An exact accretion rate was obtained by analytically solving an accretion equation without any arbitrary assumptions. It was shown that the accretion rate used previously had a shortcoming, especially in the cases where two different particles become close in mass-weighted mean fall velocity. As an improvement, a more accurate and simpler parameterization for the accretion rate was proposed based on the exact accretion rate. It was demonstrated that this parameterization was valid for various conditions of the accretion process. (MacKeen-PTT)

R. Meneghini, and K. Nakamura.
Remote Sensing of the Environment RSEEA7, Vol. 31, No. 3, p 193-209, March 1990. 10 fig, 20 ref.

Descriptors: *Radar, *Rain, *Remote sensing, *Weather, Airborne weather radar, Attenuation, Dual-wavelength radar, Liquid water content, Mathematical analysis, Rainfall rate.

One of the quantities of interest in a spaceborne weather radar is the rain rate or liquid water content as a function of height. In the presence of attenuation, however, the reconstruction of the profile is possible with usual methods only if the rain rate is uniform or if the relationships between the radar measurables and the rain characteristics are well known. Even with a dual-wavelength radar, estimates of attenuation between adjacent range gates tend to be noisy. A class of methods that are based on a measure of path attenuation which is used to constrain the Hitschfeld-Bordan solution was investigated. Methods of this type have been investigated for lidar, radar, and combined radar-radiometer applications; their functions can be interpreted as allocating the attenuation in proportion to the strength of the measured reflectivity. Four estimates of rain rate were described and tested using data from a dual-wavelength airborne radar at 10 GHz and 35 GHz. When attenuation was significant, the estimates were generally more accurate than those without attenuation correction. This suggests that such methods can be used to extend the effective dynamic range of the radar to higher rain rates. Comparisons between the estimates also provide some diagnostic capability for the detection of radar calibration errors. Instabilities in the estimates can occur, however, in cases of low signal to noise ratios and in situations where partially melted hydrometeors contribute to the attenuation. (Author's abstract)

Descriptors: *Arid lands, *Fractals, *Mathematical models, *Meteorology, *Model studies, *Rainfall distribution, *West Africa, Albedo, Burkina Faso, Network design, Random processes, Spatial distribution, Topography.

The main characteristic of West African rainfall is its great variability in time and space. This variability is difficult to study and to explain. As the influence of topography is admitted and that of albedo unconfirmed, this variability is often considered as a random process. During the rainy season of 1986, a field experiment in Burkina Faso (100 rain gauges spread over 10,000 sq km) permitted the study of the spatial variability of rainfall events by fractal geometry. A downpour observed on June 12-13, 1986 in the region was subjected to an in-depth study using fractal techniques. This permitted an evaluation of the influence of the geometric structure of the measuring network on the perception of the phenomenon under study. The technique also permitted the recognition and quantification of certain structural elements of the precipitation field, especially its anisotropy. (Rochester-PTT)

Descriptors: *Arid lands, *Meteorology, *Rainfall distribution, *Statistical analysis, *West Africa, Climates, Frequency distribution, Time series analysis.

The Lee and Heghinian statistical procedure was employed to demonstrate the non-stationarity of the West African hydrometeorological series. This non-stationarity of series led to the development of an original segmentation procedure. Since the beginning of the century the climatic evolution has experienced shifts of stationarity that are synchronous in the whole West African series. The following sequences are distinguishable: before 1906, 1907-1921, 1922-1936, 1937-1949, 1950-1968, and from 1969 to the present. The last shift, in 1968, seems a major event with the general fall in pluviometric heights. The length of these sequences varies from 13 to 20 yr and they are not cyclic. These results yield a climatic evolution with successive stages on a general downward trend toward more and more extensive aridity. Furthermore, these results challenge the hydrological standards and limit, in particular, the use of the notion of climatic means and 'normals' used to describe the years of low and abundant rainfall. Descriptors: *Rainfall distribution, *Risk assessment, *Semiarid lands, *Statistical analysis, Agriculture, Drought, France, Hydrologic mapping, Mapping, Prediction, Temporal distribution.

Information on the risks from variation in the rainfall distribution in time is indispensable for establishing the agricultural calendar. Risk definition also serves to determine which crop varieties should be cultivated. If a long dry period is expected during the usual rainy season, resistant plants should be preferred. If the risk is small, one could select plants with a growth cycle corresponding to this duration. The classical solution has been to determine empirically the distribution of pluviometric totals within short time spans (10-day or 5-day intervals). Among the problems with this method are its laboriousness and the need to work with short intervals where the errors may be great and the results cannot be mapped easily. The use of the law of gaps permits solutions to the problem without these difficulties. The law of gaps is simple because there are only two parameters: (1) distribution of time spans between two heavy rainfalls and (2) the amount of heavy rain. After the monthly adjustments, one can deduct the distribution of totals for periods shorter than 1 month and for the time separating two successive rainfalls. The results can be mapped and interpolation is feasible. It is possible to make a synthesis of all the pluviometric information from 24 maps with monthly values of each of the parameters of the law. Examples are given of the use of the method at sites in France, including mapping of the results. (See also W91-02288) (Author's abstract)

HYDROLOGICAL ASPECTS OF THE DEVELOPMENT AND RAPID DECAY OF THE 1989 DROUGHT.
Institute of Hydrology, Wallingford (England).
T. Marsh, and R. Monkhouse.
Weather WTHRAL, Vol. 45, No. 8, p 290-299, August 1990. 3 fig, 4 tab, 11 ref.

Descriptors: *Climatology, *Drought, *Great Britain, *Groundwater recharge, *Hydrologic aspects, *Hydrology, *Precipitation excess, *Runoff, *Weather, Evaporation, Groundwater level, Hydrologic budget, Local precipitation, Precipitation, Rainfall, Soil water, Water resources.

In all but a few of Great Britain's eastern districts the persistent and widespread rainfall over a 10-week period beginning in mid-December 1989 served to terminate, in dramatic fashion, a sustained drought which by the late autumn had constituted a significant threat to water resources. The notable recent variations in water resources with particular emphasis on the extraordinary transformation in hydrological conditions were examined over the 1989/1990 winter. The transformation reached a climax in February when unprecedented rates of river runoff and aquifer recharge were recorded over large areas. Exceptionally wet spells have succeeded sustained dry periods in Britain on a number of occasions, notably following the droughts of 1959, 1976, and 1984. When, as in the last two cases, the drought broke at the end of the summer, the hydrological effectiveness of the heavy rainfall was, initially, reduced by high soil moisture deficits and continuing evaporative losses. The singular nature of the water resources recovery in February 1990 owes as much to the insignificance of these factors throughout most of Britain as the abundant rainfall itself. A very dry winter, followed by an exceptionally wet one in 1989/90 resulted in monthly runoff totals and a rise and fall of groundwater levels that extended the range of recorded variations in a number of regions. Both winters were also notably mild. In water resources terms this implied an increase in evaporation losses throughout the winter--especially if the climate becomes windier--partly counteracting the benefit that a trend towards, or clustering of, wetter winters would confer. The challenge for climatologists and hydrologists is to determine whether the exceptional conditions recently experienced represent the extreme range of normal variability or are indications of a trend towards less familiar climatic territory. PRECIPITATION FLUCTUATION OVER SEMIARID REGIONS IN NORTHERN CHINA AND THE RELATIONSHIP WITH EL NINO/SOUTHERN OSCILLATION.
Atmospheric and Environmental Research, Inc., Cambridge, MA.
W. Wang, and K. Li.
Journal of Climate JLCLEL, Vol. 3, No. 17, p 769-783, July 1990. 9 fig, 4 tab, 30 ref. US DOE Grant No. DE-FG02-86-ER60422.

Descriptors: *China, *Climatic changes, *Climatology, *Desertification, *El Nino/Southern Oscillation, *Meteorological data, *Meteorology, *Precipitation, *Rainfall, *Semiarid climates, *Weather

patterns, Atmosphere-ocean interactions, Climates, Correlation analysis, Meteorological data collection, Monsoons.

Many observational studies in recent years suggest that interannual variations in rainfall at low latitudes, sometimes even at middle and high latitudes, are related to the El Nino (EN) and Southern Oscillation (SO) events in the tropics. The interaction between atmosphere and ocean caused by such exchange will have a profound effect on the global climate. In recent years the semiarid region of northern China, which has total annual precipitation between 200 and 500 mm, has shown signs of severe desertification. In this study, the 1951-86 monthly precipitation measurements in this region were used to study their fluctuations and relationships with the El Nino/Southern Oscillation (ENSO). Three main features were identified as a result of the study: (1) a 2-3 year quasi-periodic fluctuation, (2) a tendency for rainfall deficiency for the whole region during ENSO years, and (3) a significant correlation between the precipitation fluctuations in the southern part of this region and Southern Oscillation index, with the former lagging the latter by 2-5 months. These features are also evident from analysis of the proxy data during the last hundred years. (Korn-PTT)

FREQUENCY-RELATED TEMPORALLY AND SPATIALLY VARIED RAINFALL.
Army Engineer District, Fort Worth, TX.
G. R. Perry, and K. L. Shafer.
Journal of Hydraulic Engineering (ASCE) JHEND8, Vol. 116, No. 10, p 1215-1231, October 1990. 11 fig, 1 tab, 11 ref.

Descriptors: *Design storms, *Flood discharge, *Model studies, *Rainfall, *Rainfall distribution, *Rainfall-runoff relationships, *Storm runoff, Catchment areas, Drainage patterns, Flood control, Spatial distribution, Temporal distribution, Texas, Watersheds.

A frequency-related design storm with spatial and temporal variation was derived from basic statistical properties. An analysis was performed to determine the impact of the spatially varied (proposed) rainfall pattern on a watershed on Tenmile Creek in Dallas County, Texas. The results of the experiment were as follows: (1) If a large subbasin is suddenly encountered, a peak for that subbasin may produce a secondary area of critical storm centers; (2) The critical storm center path will coincide with locations along the stream path; (3) Compared to a spatially uniform rainfall model, a spatially varied synthetic rainfall model is less efficient in the total volume of rainfall delivered to a drainage basin and more efficient in placing the volume of rainfall to achieve best effect; (4) Drainage area discontinuities appear to be an important consideration in modeling a drainage basin, as does the drainage network; and (5) The storm pattern does not affect the critical storm center for small drainage areas, but for larger basins it is presumed that the storm pattern will be a critical element. The frequency-related temporally and spatially varied rainfall analysis produces a graphical illustration of the ideal locations to construct flood control facilities. (MacKeen-PTT)

SOME CHARACTERISTICS OF POINT DISCHARGE CURRENT DURING TWO PRE-MONSOON SEASON THUNDERSTORMS AT PUNE.
Indian Inst. of Tropical Meteorology, Poona.
G. K. Manohar, S. S. Kandalgaonkar, and S. M. Sholapurkar.
Current Science CUSCAM, Vol. 59, No. 7, p 367-370, April 10, 1990. 4 tab, 18 ref.

Descriptors: *Electric currents, *Meteorology, *Monsoons, *Point discharge current, *Thunderstorms, *Weather data collections, Distribution patterns, Electric fields, Electrical studies, Frequency distribution, India.

During the periods of thunderstorms when strong electric fields exist, transfer of negative/positive charge to the earth through point discharges from surface irregularities takes place. Measurements of point discharge current were made at Pune during two pre-monsoon season thunderstorms of 1987 and 1988. The point discharging element consisted of a platinum/10% iridium needle 0.5 mm in diameter and about 2 cm long erected at a height of 14 m above the ground level. Continuous record of point discharge current was obtained. The monthly distribution of the number of days of thunderstorms in the pre-monsoon months (April, May and June) of 1987 was seen to vary from that of 1988 (0/7, 6/1, and 5/2 days, respectively), though the total number of seasonal thunderstorm days on both occasions were equal. The daily features of point discharge current on the days of thunderstorm during 1987 and 1988 are as follows. The seasonal positive charge received by the earth was +31.51 mC in 1987 and +16.14 mC in 1988. Similarly the seasonal negative charge received was -19.09 mC in 1987 and -21.79 mC in 1988. Normalized frequency distribution of spells and diurnal time duration of point discharge current and the values of charge received by the earth are also presented. Results suggest that thunderstorms in May through June contributed for excess positive charge rather than negative charge, and thunderstorms in April contributed for excess negative charge. In 1987 longer durations of positive current prevailed than those of negative and in 1988 the reverse was noticed. During 1987 an appreciable duration of point discharge current persisted even beyond mid-night hours, which was unlike that in 1988. However, since the above results are based on limited observations, these inferences should be taken with sufficient reservation and detailed verification is necessary from future works. DOPPLER-RADAR ANALYSIS OF A LOW-PRECIPITATION SEVERE STORM.
Oklahoma Univ., Norman. School of Meteorology.
H. B. Bluestein, and G. R. Woodall.
Monthly Weather Review MWREAB, Vol. 118, No. 8, p 1640-1664, August 1990. 26 fig, 61 ref, append.

Descriptors: *Convective precipitation, *Meteorology, *Radar, *Remote sensing, *Storms, Hail, Meteorological data, Oklahoma, Rain, Weather patterns, Wind.

The structure and evolution of a convective storm that formed along the dryline in Oklahoma on 26 April 1984 and developed into a supercell was studied in detail. Dual-Doppler wind analyses, analyses of surface-mesonetwork and instrumented-tower data, storm-intercept photographs, analyses of raingage data from a dense network, and storm reports were used. The storm exhibited the following low-precipitation (LP) characteristics: the absence of any strong, evaporatively cooled, storm-scale downdraft near the surface; a paucity of rain reaching the ground; large hail; long-lived rotating updrafts; and a strong, relatively small in areal extent, unicellular radar echo. The storm split, and its right-moving member developed into an isolated, high-precipitation supercell. It is suggested that the region under cloud base was associated with strong radar echo caused by widely spaced, large water droplets and hailstones. Separate cyclonically and anticyclonically rotating updrafts were found on the southern and northern flanks of the storm, respectively. The high correlation between vorticity and vertical motion is circumstantial evidence that they are dynamically related. The storm split as the updrafts on the northern and southern flanks of the LP storm developed precipitation cores, and each propagated away from the original echo. (Author's abstract)

The role of moist convective processes in the heat and moisture budgets of a June 1981 tropical squall line, observed in West Africa during the cooperative experiment COPT 81 (COnvection Profonde Tropicale), was investigated using Doppler radar observations. Condensation and evaporation through the release of latent heat, were the dominant terms in the total apparent heating profile although the melting process was also important. The total apparent moisture sink was also dominated by condensation and evaporation. However, the eddy moisture flux had an important influence on the vertical structure. The total apparent heat source was marked by a deeper layer of cooling while the total apparent moisture sink had a single peak observed in the middle troposphere. The convective-scale heating profile indicated a net cooling in the lower troposphere, mainly due to the evaporation of precipitation. This cooling could be explained by a deep subsaturated layer where convective precipitation was evaporated. The convective-region moisture sink profile exhibited drying through the full depth of the troposphere, but with a peak at middle levels. It was found that the relatively high position of the drying peak resulted from the specific contribution of the eddy moisture transport in the convective region, which was concentrated in the low-to-middle troposphere and which tended to raise the drying peak due to condensation in convective updrafts. From the particular impact of convective eddies the occurrence of a double-peaked structure in the total apparent moisture sink is proposed. It was also found that ambient air entering the system at mid levels strongly modified the vertical exchange from convective updrafts by limiting it to the lower part of the troposphere. Descriptors: *Baja California, *Climatic zones, *Climatology, *Precipitation mapping, *Weather data collections, Mexico, Physiographic provinces, Rainfall distribution, Weather patterns.

Annual pluvial precipitation patterns obtained from 57 weather stations in the southern part of the Baja California Peninsula, Mexico, during more than 20 years were analyzed. Three distinct periods are readily recognizable from the annual mean pattern: Period I corresponding to the dry season from March to June; Period II corresponding to the rainy season from July to October; Period III corresponding to the rainy season from November to February. A regionalization was obtained from the rainy regime based on the relative weight of both rainy periods, marked along the mean physiographic climatological zonal features, that in general terms correspond to the climatic zonation obtained by several authors based on different data sets. Notwithstanding the geographic distribution in accord with the mean physiographical and climatological characteristics of the study zone, a transitional climatic index is proposed which, seems to indicate that the tropical and temperate influences go beyond the regions of predominance. The variability of some casual phenomena associated with the zonal weather tendencies also were analyzed by means of an original interpretation of harmonic analysis. (Author's abstract)

LIQUID WATER CONTENT AND PRECIPITATION CHARACTERISTICS OF STRATIFORM CLOUDS AS INFERRED FROM SATELLITE MICROWAVE MEASUREMENTS.
Pennsylvania State Univ., University Park. Dept. of Meteorology.
J. A. Curry, C. D. Ardeel, and L. Tian.
Journal of Geophysical Research (D) Atmospheres JGRDE3, Vol. 95, No. 10, p 16,659-16,671, September 20, 1990. 13 fig, 3 tab, 55 ref.

Descriptors: *Cloud liquid water, *Meteorology, *Microwaves, *Precipitation, *Remote sensing, *Satellite technology, Atmospheric water, Cloud physics, Clouds, Data acquisition, Radiometry.

An analysis of the integrated liquid water content and precipitation characteristics of stratiform clouds using data from Nimbus 7 Scanning Multichannel Microwave Radiometer (SMMR) for January 1979, over the North Atlantic Ocean is presented. Concurrent analysis of the SMMR data with the US Air Force 3-Dimensional Nephanalysis (3DNEPH) allows the interpretation of the SMMR-derived liquid water paths and precipitation characteristics in terms of cloud type, cloud fraction, and cloud height. Combining the initialized analyses from the European Center for Medium Range Weather Forecasting (ECMWF) with the 3DNEPH enables vertical temperature and humidity profiles to be incorporated into the retrievals. The average liquid water paths for middle and low clouds were determined to be 115 and 102 g/sq m, respectively, with a maximum value of 1070 g/sq m. Analysis showed that the clouds were substantially diluted by a combination of precipitation, freezing and entrainment. Analysis of the liquid water path as a function of temperature showed that clouds with average temperatures below 246 K had very little liquid water, and were inferred to be predominantly crystalline. There was little evidence that the cloud liquid water path increases with temperature for cloudiness on a large scale, suggesting that cloud thickness plays the dominant role in determining cloud liquid water path. A total of 8.5% and 4.4% of the total middle and low clouds, respectively, were determined to be raining. Liquid water paths of 350 g/sq m and 55 g/sq m for middle and low clouds, were determined to be average thresholds for the onset of precipitation. Maximum rain rates for these clouds were determined to be 7 mm/h. The autoconversion of cloud water to rain water was determined to occur at a rate of 0.001/s. (Lantz-PTT)

Journal of Geophysical Research (D) Atmospheres JGRDE3, Vol. 95, No. 10, p 16,673-16,683, September 20, 1990. 5 fig, 5 tab, 40 ref. ARO Grant No. DAAL03-86-G-0190.

Descriptors: *Cloud liquid water, *Meteorology, *Microwaves, *Remote sensing, Atmospheric water, Data acquisition, Radiation, Radiometry, Satellite technology, Temperature.

Techniques for cloud liquid water retrieval over land are developed using data from the Special Sensory Microwave/Imagery 85.5 GHz (3.5 mm) channels. To minimize the effect of surface emittance variability on the calculations, the surface emittance was estimated with the aid of surface skin temperature retrievals from the Visible Infrared Spin Scan Radiometer in geosynchronous orbit. The high sensitivity of the 85.5 GHz channels to cloud liquid water allows for the estimation of integrated cloud liquid water based on the microwave brightness temperature depression caused by attenuation and emission of microwave radiation at the colder ambient temperature of the cloud. The method assumes non-scattering radioactive processes are dominant; therefore, only non-precipitating cloud liquid water is considered. Integrated cloud liquid water retrievals show good qualitative agreement with other available data sources. Numerical error sensitivity analysis showed integrated cloud liquid water error estimates of 0.05-0.50 kg/sq m depending on the contrast of cloud over background. (Author's abstract)

PRECIPITATION CHEMISTRY IN CENTRAL AMAZONIA.
Florida State Univ., Tallahassee. Dept. of Oceanography.
M. O. Andreae, R. W. Talbot, H. Berresheim, and K. M. Beecher.
Journal of Geophysical Research (D) Atmospheres JGRDE3, Vol. 95, No. 10, p 16,987-16,999, September 20, 1990. 12 fig, 4 tab, 57 ref. NASA Tropospheric Chemistry Program Grant No. NAG-1-588.

Descriptors: *Acid rain, *Amazon River Basin, *Chemistry of precipitation, *Path of pollutants, *Water pollution sources, Aerosols, Chlorides, Fluctuations, Nitrates, Organic acids, Potassium, Precipitation, Seasonal variation, Sodium, Statistical analysis, Sulfates, Tropical regions.

Rain samples from three sites in central Amazonia were collected over a period of 6 weeks during the 1987 wet season and analyzed for ionic species and dissolved organic carbon. A continuous record of precipitation chemistry and amount was obtained at two of these sites, which were free from local or regional pollution, for a period of over one month. The volume weighted mean concentrations of most species were about a factor of 5 lower during the wet season. Only Na, K, and Cl2 showed similar concentrations in both seasons. When the seasonal difference in rainfall amount is taken into consideration, the deposition fluxes are only slightly lower for most species during the wet season than during the dry season, again with the exception of Cl2, Na, and K. Na and Cl2 are present in the same ratio as in sea salt; rapid advection of air masses of marine origin to the central Amazon Basin during the wet season may be responsible for the observed higher deposition flux of these species. Statistical analysis suggests that sulfate is, to a large extent, of marine (sea salt and biogenic) origin, but that long range transport of combustion derived aerosols also makes a significant contribution to sulfate and nitrate in Amazonian rain. Organic acid concentrations in rain were responsible for a large fraction of the observed precipitation acidity; their concentration was strongly influenced by gas/liquid interactions. (Author's abstract)

Journal of Geophysical Research (D) Atmospheres JGRDE3, Vol. 95, No. 10, p 17,001-17,014, September 20, 1990. 16 fig, 5 tab, 32 ref. NSF Grant No. ATM85-18826.

Descriptors: *Amazon River Basin, *Chemistry of precipitation, *Climatology, *Data interpretation, *Hydrologic budget, *Meteorology, *Rainfall, *Satellite technology, Acetates, Acid rain, Aerosols, Formates, Meteorological data collection, Pyruvates, Rainfall intensity, Remote sensing, Sulfates, Tropical regions.

Meteorological and chemical data collected during the wet season Amazon Boundary Layer Experiment near Manaus, Brazil, were used to investigate the rainfall, rainfall systems, and surface kinematics of the south central Amazon basin wet season. Analysis of the Geostationary Operational Environmental Satellite (GOES-West) imagery indicated that, based on location of initial development, there are three main types of convective systems which influence a mesoscale network near Manaus. Coastal Occurring Systems (COS) are mesoscale to synoptic scale sized systems of generally linear orientation which form along the northern coast of Brazil and propagate across the Amazon Basin. The Basin Occurring Systems (BOS) form in the basin east and north of Manaus and also propagate toward the network. Locally Occurring Systems (LOS) form in and around the mesoscale network and rarely are larger than 1000 cu km. Composites of hourly rainfall totals and satellite derived cloud cover show that rainfall and cloudiness associated with COS occurred in the network between 1000 and 1400 UT. Little rain or cloud cover was seen before 1600 UT during days influenced by LOS. Chemical analysis of the rain water delivered by these systems also shows significant differences in the concentrations of formate, acetate, pyruvate, sulfate, and hydrogen ion. In addition, aerosol concentrations measured near Manaus indicate large influxes of aerosols (Na, Cl, and Si) into central Amazonia after the passage of BOS and COS. During April 11-20, BOS occurred on 8 days and produced 98% of the rainfall. Eight COS occurred during April 21 to May 3 and accounted for 89% of the rainfall. The final part of the experiment, May 4-14, was influenced solely by LOS. Harmonic analysis of surface divergence during this period exhibits a peak at 24 hours. This peak, representing the diurnal heating cycle, does not exist earlier in the experiment when BOS and COS are more frequent. (Author's abstract)

ESTIMATES OF DAILY RAINFALL OVER THE AMAZON BASIN.

Wisconsin Univ.-Madison. Space Science and Engineering Center.
D. W. Martin, B. Goodman, T. J. Schmit, and E. C. Cutrim.
Journal of Geophysical Research (D) Atmospheres JGRDE3, Vol. 95, No. 10, p 17,043-17,050, September 20, 1990. 6 fig, 5 tab, 20 ref. NSF Grant No. ATM-8703966.

Descriptors: *Amazon River Basin, *Data acquisition, *Rainfall, *Remote sensing, Mapping, Maps, Meteorology, Rain gages, Rainfall distribution, Satellite technology, Surveys, Temperature, Tropical regions.

Five geostationary satellite rain estimation techniques were tested over Amazonia. Individually, the techniques explained 1/4 to 1/3 of the variance of daily gage rainfall. Based on large part on cost, one technique which involves a nonlinear relation in temperature, was selected to provide a mapping of daily Amazonia rainfall between May 6 and 12, 1987. Accumulated over seven days, rainfall by this technique averaged 40 mm. It varied from zero in the southeast to more than 150 mm in the northwest. To the southwest the predominantly convective pattern of the rain image was overlaid by a streakiness, implying some baroclinic influence. In maps combining gage observations with satellite estimates, rainfall varied significantly from day to day. Only over the largest scale did a trend emerge--a tendency for rain to withdraw from south to north. (Author's abstract)

CLIMATIC INFLUENCES ON STREAMFLOW VARIABILITY: A COMPARISON BETWEEN SOUTHEASTERN AUSTRALIA AND SOUTHEASTERN UNITED STATES OF AMERICA.
Melbourne Univ., Parkville (Australia). Dept. of Civil and Agricultural Engineering.
I. Kuhnel, T. A. McMahon, B. L. Finlayson, A. Haines, and P. H. Whetton.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2483-2496, October 1990. 9 fig, 3 tab, 42 ref.

Descriptors: *Australia, *Climates, *Climatology, *Rainfall, *Rainfall-runoff relationships, *Runoff, *Stream discharge, *Streamflow forecasting, Atmospheric circulation, Comparison studies, Flow rates, Seasonal distribution, Southern oscillation.

Differences in runoff and rainfall variability between southeastern Australia and southeastern United States have been examined, using various standard techniques such as principal component and spectral analyses, and examination of the quick and base flow components of runoff. The higher runoff variability in Australia can be explained, in part, by the large-scale circulation and rainfall patterns associated with the Southern Oscillation which are unlike those in the southeastern United States. Whereas the Southern Oscillation signal is easily detectable in the southeast Australian rainfall and runoff data, it is, with the exception of several small areas, absent in the southeastern United States data. In the case of this particular comparison, the differences in runoff variability between the two selected regions were found to be largest in winter and spring months and smallest in summer. Among the continents, Australia shows the strongest impact of the Southern Oscillation, and the different rainfall and runoff variability in the two specific regions is likely to be similar when comparing Australia with any other part of the world. PERIODIC-STOCHASTIC MODELING OF SEPARATION OF PRECIPITATION INTO RAINFALL AND SNOWFALL.
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
V. Yevjevich, and N. B. Harmancioglu.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2613-2623, October 1990. 17 fig, 1 tab, 23 ref. National Science Foundation Grant CEE-8405289/8541631.

Descriptors: *Model studies, *Precipitation, *Rainfall, *Runoff, *Snowfall, *Stochastic models, Distribution, Fourier analysis, Markov process, Mathematical models, Probability distribution, Statistical analysis.

Modelers must separate precipitation into rainfall and snowfall because the two processes have significant differences as input to runoff. The purpose of the present study is to model this separation, provided that available data permit the coding of observed precipitation as rainfall, snowfall, and/or mixed rainfall-snowfall. Modeling of precipitation is realized by a simple approach such as the periodic-stochastic Markov chain description of occurrence and nonoccurrence of time interval precipitation. The exponential probability distribution based function, with periodic parameters, are is for modeling the nonzero values of precipitation. The generated series are then separated into rainfall and snowfall components by means of the rainfall-precipitation ratio. This ratio is modeled as a periodic-stochastic process in the range zero to one. The bounded (0,1)-beta distribution function is selected as the appropriate distribution function to describe the ratio when it can also assume values between zero and unity. Most parameters in modeling precipitation and the ratio show periodicity, often fitted well by one-harmonic and two-harmonic Fourier functions. Two sets of daily precipitation series, each ten years long, are used to demonstrate the results of modeling daily precipitation and daily rainfall-precipitation ratio: the Bansanson precipitation gauging station in the Durance River basin, France (as a point process), and the W-3 watershed area, near Danville, Vermont (as a daily average areal precipitation process). The investigation shows the feasibility of modeling the separation when observed precipitation is coded for rainfall, snowfall, or mixed rainfall-snowfall. (Brunone-PTT)

Descriptors: *Chernobyl, *Data acquisition, *Fallout, *Glacier mass balance, *New snow, *Radioactivity, *Tracers, Glaciers, Snow accumulation, Snow sampling.

Glacial mass balance determination in the accumulation zone is accomplished by the determination of the water equivalent of the fresh snow cover. Radioactive fallout due to the Chernobyl accident on April 26th, 1986, has already been identified in Northern hemisphere glaciers, where it has provided a new reference level. An in situ gamma ray spectrometer was developed in order to detect the radiation from Chernobyl directly in the field. Therefore the depth of the Chernobyl layer can be determined. The optical properties of ice clouds are a primary issue for climate and climate change. Evaluating these optical properties in three-dimensional models for studying climate will require a method to calculate the ice water content of such clouds. A procedure is developed to parameterize ice water content as a function of large-scale meteorological characteristics for use in circulation models, in which the ice water content is not calculated by means of a three-dimensional prognostic equation for condensed water. The technique identifies large-scale flows in which ice clouds exist and calculates their ice water content by reconstructing the trajectory associated with cloud formation. As the cloud forms, its ice content changes both by deposition of ice from water vapor and by ice removal by sedimentation. The sedimentation process is found to significantly modify the ice water content expected from deposition alone. Ice water contents predicted by the parameterization were compared with aircraft observations collected in the middle latitudes and the tropics, and show reasonable agreement over four orders of magnitude of ice and water content. A parameterization for the sublimation of ice crystals settling into ice-subsaturated environments has also been developed. (Author's abstract)

PHYSICS OF SUPERCOOLING OF THIN WATER SKINS COVERING GYRATING HAILSTONES.
Toronto Univ. (Ontario). Dept. of Physics.
R. List.
Journal of the Atmospheric Sciences JAHSAK, Vol. 47, No. 15, p 1919-1925, August 1990. 7 fig, 10 ref.

Descriptors: *Atmospheric physics, *Freezing, *Hail, *Precipitation, *Supercooling, Air-water interfaces, Heat transfer, Ice formation, Ice-water interfaces, Physical analysis.

Liquid water skins on spongy deposits of hailstones that grow while gyrating in a wind tunnel environment, have been routinely observed to be supercooled at the water skin-air interface to as low as -5 C. The average water skin thickness (up to 1 mm) in the main growth region was calculated on the basis of the molecular conduction of the latent heat of freezing from the spongy substrate at the base of the water skin to its surface. This heat transfer is gradient-driven and relates directly to the speed of ice accretion on the hailstone. Extrapolation of an equation for the ice growth speed in supercooled bulk water suggested a supercooling of the ice-water interface on the order of -0.3 C. The physical picture which emerged, was that

of an ice sponge from which a fragile dendrite mesh grows into the water skin with a very homogeneous front, and an advance speed that is controlled by the diffusion of heat (heat conduction) away from the ice front. Combining all results, it can be categorically stated that all surface points of growing hailstones have temperatures below the freezing point of water. (Author's abstract)

FIELD FROST HEAVE MEASUREMENT AND PREDICTION DURING PERIODS OF SEASONAL FROST.
Agriculture Canada, Ottawa (Ontario). Land Resource Research Centre.
H. N. Hayhoe, and D. Balchin.
Canadian Geotechnical Journal CGJOAH, Vol. 27, No. 3, p 393-397, June 1990. 8 fig, 1 tab, 12 ref.

Descriptors: *Data acquisition, *Electrical equipment, *Freezing, *Frost heaving, *Instrumentation, *Thermocouples, Canada, Cultivation, Loam, Soil properties, Soil temperature, Temperature gradient.

Frost heave measurements were taken over two winter seasons on a clay loam soil located near Ottawa, Canada. Heaving was measured using linear displacement transducers attached to a metal frame that was anchored in the soil below the depth of frost penetration. The output of the displacement transducer was recorded hourly using a microcomputer based data logger. The system functioned reliably and the observed data compared well with published measurements. Soil temperature was recorded simultaneously using thermocouples placed at various depths up to 1 m. Time-domain reflectometry was used to measure the unfrozen water content at approximately two week intervals. The study shows that soil temperature measurements can be used to estimate the temperature gradient at the freezing front for determining the cumulative frost heave, as suggested by the Konrad-Morgenstern theory of ice segregation processes. The results also support the observation that tilled soils are more susceptible to heave than undisturbed soils. (Author's abstract)

RECONSTRUCTION AND DYNAMICS OF THE LATE WISCONSIN 'ONTARIO' ICE DOME IN THE FINGER LAKES REGION, NEW YORK.
Maryland Univ., College Park. Dept. of Geology.
R. W. Ridky, and R. A. Bindschadler.
Geological Society of America Bulletin BUGMAF, Vol. 102, No. 8, p 1055-1064, August 1990. 5 fig, 2 tab, 67 ref.

Descriptors: *Finger Lakes, *Glacial drift, *Glacier mass balance, *Glaciers, *Glaciology, *Ice thickness, *New York, Drumlins, Glacial sediments, Ice pressure, Mathematical models, Shear stress.

Distribution of drumlins on the Ontario Lowlands and the northern Appalachian Plateau of New York State are utilized in a glaciological model that estimates thicknesses of the Late Wisconsin Ice Sheet along five glacial flowlines over the central section of the Finger Lakes. Dynamics of the model are based upon a force balance approach that incorporates variable width of a flowband, bedslope, radius of curvature, and center of outflow location. Drumlin axes along five hydrostatic isograms were projected northward. Points of axes convergence define the center of outflow in the eastern Ontario Basin. Flowlines along the axial trace of the major Seneca and Cayuga Troughs and bordering interfluves were constructed southward to the Valley Heads Moraine System. Calculation of flowline geometry for any assumed basal shear stress requires neither information on ice temperature nor the flow law of ice. Ice thicknesses for each flow line were calculated for various basal shear stresses. Ice thicknesses at 1 bar range from a minimum of 1,932 m for the Seneca Trough flowline to a maximum of 2,093 m at the Keuka-Seneca interfluve. Simulating ice recession, a series of ice-marginal, terminal positions were plotted for a basal shear stress of 1 bar. These predicted terminal positions agree well with locations of mapped moraine deposits. These probable values of basal shear stress support the presence of glacial flow representative of internal deformation rather than basal sliding. This evidence discounts the presence of ice streams and supports the existence of outlet glaciers in the troughs of the Finger Lakes. (Author's abstract)

FAST-FLOWING OUTLET GLACIERS ON SVALBARD ICE CAPS.
Scott Polar Research Inst., Cambridge (England).
J. A. Dowdeswell, and R. L. Collin.
Geology GLGYBA, Vol. 18, No. 8, p 778-781, August 1990. 5 fig, 18 ref. United Kingdom Natural Environment Grant GR3/4663.

Descriptors: *Glacier balance, *Glacier mass balance, *Glaciers, *Glaciohydrology, *Svalbard, Aerial photography, Arctic zone, Glacial streams, Remote sensing, Satellite technology.

Fast-flowing outlet glaciers and ice streams provide a mechanism for the rapid discharge of mass from ice sheets, implying that their dynamic behavior through time is of particular significance to the stability of the parent ice mass. Four well-defined outlet glaciers are present on the 2510 sq km ice cap of Vestfonna in Nordaustlandet, Svalbard. Airborne radio echo sounding and aerial photograph and satellite image analysis methods have been used to analyze the morphology and dynamics of the ice cap and its component outlet glaciers. The heavily crevassed outlets form linear depressions in the ice cap surface and flow an order of magnitude faster than the ridges of uncrevassed ice between them. Ice flow on the ridges is accounted for by internal deformation alone, whereas rates of outlet glacier flow require basal motion. One outlet has recently switched into and out of a faster mode of flow. Rapid terminal advance, a change from longitudinal compression to tension, and thinning in the upper basin indicate surge behavior. Observed outlet glacier discharge is significantly greater than current inputs of mass to the ice cap, indicating that present rates of flow cannot be sustained under the contemporary climate. A thermal infrared image provides information about crop evapotranspiration in a certain area at flight time. A simple method has been developed to convert instantaneous crop temperatures into 24-h evapotranspiration values. For clear days, good results were obtained with a linear relationship between relative 24-h evapotranspiration and the increase in crop temperature around mid-day. The crop temperature is related to the temperature of the crop that is potentially transpiring. For the typical flight days to detect crop stress conditions, the empirical coefficient B(r) appeared to be almost insensitive to variations in air temperature, relative humidity, and incoming radiation flux. On the other hand, B(r) was strongly dependent on wind velocity, crop type, and crop height. Information about crop type and crop height can be derived from reflection images. The wind velocity can be obtained from a nearby meteorological station. Overall, the method appears to be suited to the automatic mapping of 24-h evapotranspiration values with the aid of digital reflection and thermal infrared images. However, application of the method requires plots with full soil overage. (Author's abstract)

The climatic changes which are expected to result from man-made atmospheric pollution will undoubtedly affect the natural hydrologic cycle. Models which will address the effect of man-made pollution on recharge rates to groundwater must take into account changes in the rate of evaporative loss (EL). Any geochemical model for the estimation of EL would be based upon a comparison between the concentration of some hydrophilic ion in a sample of resource water to the concentration of that ion in precipitation. A method has been developed comparing the chloride concentration and the ratio of Cl36 to total chloride of a given water body to those of precipitation to determine the fraction of the original precipitation which was lost by evapotranspiration before it reached that water body. This method was applied to 11 water sources in the upper Jordan River basin, and the evapotranspirative loss was generally found to be in the range 40-90%. This method, which is much simpler than the other methods for determining regional evapotranspiration, will enable us to mon-

itor the changes in the hydrological cycle which are expected to result from the greenhouse effect. (Tappert-PTT)

IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 169-180, 11 ref. English summary.

Descriptors: *Africa, *Arid lands, *Evaporation, *Hydrologic budget, *Sahel, *Sudan, Climates, Estimating equations, Penman formula, Water resources management.

In the Sudano-Sahelian zone of Africa, evaporation is the most important parameter of the water balance. How to plan the management of water is problematical when this parameter is inadequately estimated, even when it exceeds precipitation by 2-10 times. Similarly, agricultural consumption is not sufficiently known, making irrigation calculations difficult. To evaluate the evaporation, the engineer must rely on data derived from nearby sites. Questions will remain concerning (1) whether there is a water management plan from which one could draw a hydrological balance; (2) whether there are climatological references stations, whether they are equipped with evaporation pans and, if so, of what type; and (3) whether all parameters are known for application of the Penman formula. Area scales (size of the water body) and time scales (time intervals in which evaporation has been determined) are reliable determinants as well. All formulas are not comparable if area and time scales are not identical. Methods described and compared here include: hydrologic balance, evaporation pan methods, the energetic approach, and evaporation from free water surfaces based on a global aerodynamic transfers. ESTIMATES OF EVAPOTRANSPIRATION WITH A ONE- AND TWO-LAYER MODEL OF HEAT TRANSFER OVER PARTIAL CANOPY COVER.
Agricultural Research Service, Beltsville, MD. Hydrology Lab.
W. P. Kustas.
Journal of Applied Meteorology JAMOAX, Vol. 29, No. 8, p 704-715, August 1990. 7 fig, 3 tab, 55 ref, append.

Descriptors: *Canopy, *Evapotranspiration, *Heat transfer, *Model studies, *Remote sensing, Cotton, Eddy correlation, Heat flux, Temperature, Weather.

One of the applications of remotely sensed surface temperature is to determine the latent heat flux or evapotranspiration from field to regional scales. Surface-air temperature differences have been successfully applied over uniform terrain with nearly full, actively transpiring vegetative cover; however, serious discrepancies between estimated and measured evapotranspiration have been observed when there is partial canopy cover. In an attempt to improve the estimates of heat flux and as a result compute more accurate values of evapotranspiration over partial canopy cover, one-layer and two-layer resistance models were developed to account for some of the factors causing the poor agreement between computed and measured evapotranspiration. The utility of these two approaches for estimating evapotranspiration at the field scale is tested with remotely sensed and micrometerological data collected in an arid environment from a furrowed cotton field with 20% cover and a dry soil surface. The estimates of latent heat flux were compared with values measured using eddy correlation and energy balance methods. It was found that the one-layer model generally performed better than the two-layer model under these conditions; but only when using a bluff-body correction to the resistance based on a conceptual model of heat and water vapor transfer at the surface taking place by molecular diffusion into Kolmogorov-scale eddies. The empirical adjustment to the surface resistance with the one-layer approach assumed to be applicable for a fairly wide range of conditions was found to be inappropriate. This result is attributed to the significant size of the furrows relative to the height of the vegetation. Furthermore, a sensitivity analysis showed that the one-layer model with the empirical adjustment for the resistance was significantly affected by the changes in the surface roughness, whereas the physically based bluff-body correction was relatively insensitive to these variations. For the two-layer model, a large change in the input variable for computing soil evaporation had a relatively small impact on the computed fluxes while a significant change in the leaf area index appeared to amplify the deviations between measured and modeled latent heat flux-values. Descriptors: *Evapotranspiration, *Remote sensing, *Simulation analysis, Albedo, Canopy, Energy, Evaporation, Model studies, Radiation, Reflectance, Soil-water-plant relationships, Stress, Transpiration, Vegetation.

The SAIL canopy reflectance model was incorporated into the TERGRA model to simulate water and energy flows in the soil-plant-atmosphere system. The reflectance model was structured to calculate canopy albedo throughout the simulation period of TERGRA and to determine spectral reflectances at a specified time during the day. Spectral vegetation indices were then calculated from the reflectances, and related to the evapotranspiration and thermal response of the canopy. Stomatal resistances were calculated from these PAR values and integrated to give the minimum canopy resistance. Actual canopy resistances were obtained by considering environmental stresses, modeled by TERGRA, such as leaf water potential and leaf temperature. Using data from a soybean canopy, canopy evapotranspiration and temperatures were simulated for a range of leaf area index values and compared with the corresponding spectral indices of green vegetation. Results indicated that the normalized difference spectral index has an inverse linear relationship with canopy temperature, concurring with results obtained from satellite observations. The possibility of using a spectral vegetation index and thermal observations together to parametize surface moisture availability for evapotranspiration is considered. ESTIMATING AREAL EVAPOTRANSPIRATION BY COMBINING REMOTE AND GROUND-BASED DATA.
Agricultural Research Service, Phoenix, AZ. Water Conservation Lab.
R. D. Jackson.
IN: Remote Sensing Applications for Consumptive Use (Evapotranspiration). Papers Presented at 21st Annual AWRA Conference and Symposium, August 11-16, 1985, Tucson, Arizona. AWRA Monograph Series No. 6, (1985). p 13-23, 7 fig, 21 ref.

Descriptors: *Evapotranspiration, *Remote sensing, Albedo, Data acquisition, Radiation, Reflectance, Solar radiation, Spatial distribution, Temperature.

Evaluating transpiration on a field-by-field basis over relatively large areas can be accomplished by combining remotely sensed data with ground based measurements. Reflected solar radiation and surface temperatures vary spatially, but can be determined by multispectral measurements. Incoming solar and sky radiation can be considered to be uniformly spatially distributed (for cloudless skies). Thus, their measurement at one location can be extrapolated over an extended area. Combining remote and ground based data allows the spatial distribution of net radiation and evapotranspiration (ET) to be mapped. The evapotranspiration calculation also requires that air temperature and wind speed be areally extrapolated. The spatial variability of these two parameters may be the limiting factor in mapping evapotranspiration over large areas. Data are presented that show a comparison of remote values with traditionally measured values of reflected solar radiation, net radiation and evapotranspiration. The areal extent over which reliable ET estimates can be made depend on the distance that the ground measured parameters can be extrapolated. Calculations indicate that the extrapolation of air temperature and wind speed may be the limiting factors. (See also W91-02594) (Lantz-PTT)

ESTIMATES OF CONSUMPTIVE USE AND EVAPOTRANSPIRATION IN PALO VERDE VALLEY, CALIFORNIA, 1981 AND 1983.
Geological Survey, Tucson, AZ. Water Resources Div.
L. H. Raymond, and S. J. Owen-Joyce.
IN: Remote Sensing Applications for Consumptive Use (Evapotranspiration). Papers Presented at 21st Annual AWRA Conference and Symposium, August 11-16, 1985, Tucson, Arizona. AWRA Monograph Series No. 6, (1985). p 25-34, 6 tab, 6 ref.

Descriptors: *Consumptive use, *Data interpretation, *Evapotranspiration, *Palo Verde Valley, *Remote sensing, Colorado River, Crops, Data acquisition, Hydrologic budget, Landsat, Satellite technology, Vegetation.

Consumptive use was calculated in 1981 and 1983 using a water budget, and evapotranspiration was calculated using vegetative types and acreage determined from Landsat digital-image analysis and two sets of water-use rates. Evapotranspiration ranged from 73-85% of consumptive use in 1981 and 91-105% in 1983. Crop acreage and flow in the Colorado River in 1981 were more representative of normal conditions in the valley than were those in 1983, but rainfall in 1981 was 68% below average. Evapotranspiration calculated using vegetation acreage is dependent on water use rates that were developed in the field for crops and phreatophytes in other areas. These water-use rates may need to be estimated on a yearly basis, rather than using an average value for each vegetation type, because of climatic changes from year to year. The 1981 data more closely represent the results to be expected in comparing consumptive use and evapotranspiration in other years than does the 1983 data. (See also W91-02594)

SLOPE, ASPECT, AND PHOSPHOGYPSUM EFFECTS ON RUNOFF AND EROSION.
Soil Erosion Research Station, Natanya (Israel).
M. Agassi, I. Shainberg, and J. Morin.
Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 1102-1106, July/August 1990. 4 fig, 2 tab, 11 ref.

Descriptors: *Erosion, *Runoff, *Slope stability, *Slopes, *Soil amendments, *Soil erosion, *Soil stabilization, Erosion rates, Field tests, Israel, Phosphogypsum, Rain gages, Rainfall, Rainfall-runoff relationships.

The effect of slope, aspect (windward vs. leeward), and phosphogypsum (PG) application on rain amount, runoff, and erosion from a Grumusol soil (Typic Chromoxerert in Israel) was measured in small field plots (1 by 1.5 m) exposed to natural rainstorms. The amount of effective rain on the slopes, as measured with small rain gauges with orifices in a plane parallel to the slope, increased slightly on the windward aspect as slope increased to approximately 58% and decreased thereafter. On the leeward aspect, the amount of effective rain dropped steadily to half of the meteorological rain at a slope of 100%. The amount of runoff was not affected by slope on the windward aspect but decreased sharply on the leeward aspect as slope increased. PG releases electrolytes into the percolating and runoff water, prevents dispersion of the particles at the surface, stabilizes the soil structure and reduced soil erosion. PG applied at 5 Mg/ha reduced runoff to about 25% of that in the control and reduced soil loss to 1 to 3% of that in the control. The dramatic effect of PG on erosion increased with increased slope steepness. (Author's abstract)

Descriptors: *Overland flow, *Precipitation, *Rainfall distribution, *Rainfall intensity, *Rainfall-runoff relationships, *Surface runoff, Finite element method, Infiltration, Roughness, Runoff, Scale factors, Spatial variability, Statistical methods, Storm runoff, Topography.

The influence of the spatial variability of rainfall precipitation, infiltration, surface roughness and surface topography on surface runoff characteristics has been widely recognized in hydrology. One-dimensional finite element models enable physically based investigations of overland flow generated under spatially varied surface slope, width, roughness, and excess rainfall intensity. Simulated results of 8400 dimensionless hydrographs under spatially varied input parameters indicate that runoff discharge variations depend primarily on the ratio of rainfall duration t(r) to the time to equilibrium t(e). Peak discharge distributions change drastically as the dimensionless rainfall duration t(r)/t(e) approaches unity. Similarity conditions exist for all four parameters regardless of whether the spatial variability is correlated or uncorrelated. A length scale function of not only the spatially averaged values of surface parameters but also depending upon rainstorm duration and intensity delineates similarity conditions for spatially varied surface runoff. For surface runoff lengths much shorter than this length scale, the rainfall-runoff relationship becomes nearly independent of the spatial variability in hydrologic parameters. Conversely, for surface runoff lengths exceeding the length scale, the rainfall-runoff relationship is sensitive to spatial variability. This length scale can serve as a basis for the determination of grid sizes in hydrologic models. (Author's abstract)

ANALYSIS OF WATER SURFACE AND FLOW DISTRIBUTION FOR THE DESIGN FLOOD AT A PROPOSED HIGHWAY CROSSING OF THE SABINE RIVER NEAR TATUM, TEXAS.
Geological Survey, Austin, TX. Water Resources Div.
J. J. Gilbert, and D. R. Myers.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 88-4231, 1989. 36p, 18 fig, 5 tab, 11 ref.

Descriptors: *Design floods, *Design flow, *Finite element method, *Flow models, *Highway relocation, *Model studies, *Sabine River, *Texas, Flood plains, Floods, Model testing, Simulation, Tatum.

The hydraulic effects of the proposed Texas Highway 43 crossing of the Sabine River were determined using a two-dimensional finite-element surface-water flow model (FESWMS). In the planning of the crossing by the Texas State Highway Department, accurate approximations of apportionment of flow among the openings and velocities within the openings were of concern. The model was used to simulate flow in the river floodplain system for the proposed crossing design, an alternate crossing design, and for the natural conditions. The alternate design more closely represents the existing bridge widths. Preliminary one-dimensional computations were used as an aid in establishing the boundary conditions for the two-dimensional analysis. The simulations show that, among other things, a proposed lengthening of the right overflow bridge is not beneficial. The alternate design is one that does not include the proposed lengthening of the right overflow bridge or the proposed construction of a new embankment at the existing main channel opening. The results of the two-dimensional simulation of the proposed design indicate some differences in the apportionment of flow among the openings when compared to the one-dimensional proposed crossing computations. Simulations of the alternate crossing design resulted in water-surface altitudes which are slightly lower than the proposed design. The alternate design would require less modification to the existing embankment. Velocities computed at the bridge abutments using the two-dimensional model were within the design specifications of the Texas State Department of Highways and Public Transportation. (USGS)

Descriptors: *Anclote River, *Estuaries, *Florida, *Saline-freshwater interfaces, Regression analysis.

Direct measurements of streamflow, tides, and salinity in the Anclote River Estuary, Florida were made during the period January 1984 through May 1986; historical streamflow was compared to that measured during the study; the influence of well-field pumpage on streamflow was evaluated; and regression relations between salinity, tide, and average daily streamflow were developed. Mean monthly streamflows during the study period generally were lower than the corresponding long-term monthly averages yet representative of flows that typically enter the estuary. The influence of pumpage from individual well fields in or near the basin on streamflow was not statistically significant; the influence of total well-field pumpage, however, was significant at the 5% level. The upstream daily location of 0.44-, 5.0-, 10-, and 18-parts-per-thousand (ppt) salinity was quantified using multiple regression techniques. Streamflow

used in the analysis ranged from 2.3 to 263 cu ft/sec, and high tides ranged from 0.25 ft below to 2.76 ft above sea level. Vertical salinity profiles indicated partially to well-mixed conditions throughout the estuary during the study period. Results of the regression analyses show that streamflow has a large effect on the location of the saltwater-freshwater interface (defined as 0.44 ppt salinity) as well as water having a salinity of 5.0 ppt. The location of water having salinities greater than 5.0 ppt is affected increasingly by tide, with a corresponding decrease in effect by streamflow. (USGS)

POTENTIAL HAZARDS FROM FLOOD-FLOWS IN GRAPEVINE CANYON, DEATH VALLEY NATIONAL MONUMENT, CALIFORNIA AND NEVADA.
Geological Survey, Sacramento, CA. Water Resources Div.
J. C. Bowers.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 89-4063, 1990. 19p, 2 fig, 3 tab, 7 ref, 1 plate.

Descriptors: *California, *Death Valley National Monument, *Flash floods, *Flood flow, *Flood frequency, *Flood recurrence interval, *Nevada, Arid-zone hydrology, Channel erosion, Cross-sections, Discharge, Drainage basins, Flood profiles, Grapevine Canyon, Inundation, Mudflows, Regional analysis, Scottys Castle.

Grapevine Canyon is on the western slope of the Grapevine Mountains in the northern part of Death Valley National Monument, California and Nevada. Grapevine Canyon Road covers the entire width of the canyon floor in places and is a frequently traveled route to Scotty's Castle in the canyon. The region is arid and subject to flash flooding because of infrequent but intense convective storms. When these storms occur, normally in the summer, the resulting floods may create a hazard to visitor safety and property. Historical data on rainfall and floodflow in Grapevine Canyon are sparse. Data from studies made for similar areas in the desert mountains of southern California provide the basis for estimating discharges and the corresponding frequency of floods in the study area. Results of this study indicate that high-velocity flows of water and debris, even at shallow depths, may scour and damage Grapevine Canyon Road. When discharge exceeds 4,900 cu ft/sec, expected at a recurrence interval of between 25 and 50 years, the Scotty's Castle access road and bridge may be damaged and the parking lot partly inundated. A flood having a 100-year or greater recurrence interval probably would wash out the bridge and present a hazard to the stable and garage buildings but not to the castle buildings, whose foundations are higher than the predicted maximum flood level. Descriptors: *Computer models, *Mathematical models, *Model studies, *Open-channel flow, *Streamflow, *Unsteady flow, Differential equations, Finite element method, Hydrodynamics, Mathematical analysis, Numerical analysis, River flow.

A robust numerical model is presented for the computation of unsteady streamflow on steep river slopes. The one-dimensional model uses the method of characteristics on a specified space-time grid to solve the Saint-Venant equations. An additional continuity equation requirement on each space-time element provides greatly improved conservation of mass over traditional implementations of the method of characteristics on a fixed grid. The space-time geometry of the problem is described in a finite element setting. Hermite interpolation of channel parameters is used to avoid numerical difficulties that may occur with steep slopes due to discontinuities in the derivatives of data such as channel top width. Manning's equation for friction slope can be modified by a factor to make the slope more appropriate for steep rivers. The standard Manning's friction slope can also be used, if preferred. The computer model is not restricted to steep slopes, and applies as well to gently sloping streams. Two numerical examples support the mathematical approach and computational algorithm. (USGS)

Descriptors: *Estimating, *Flood frequency, *Frequency analysis, *Prediction, *Regional floods, Arkansas River Basin, Colorado, Colorado River Basin, Flood data, Illinois, Model studies, Planning, Regional analysis, Rio Grande Basin.

The overall objective of the research has been to develop flood frequency models and estimation methods for prediction of floods at gaged and ungaged watersheds. Several topics were studied under this project including, estimation of Pearson III model, properties and estimation of non-conventional distributions such as mixture models, and regional maximum likelihood estimation (MLE). In addition, applications to flood data in Colorado and Illinois regions were made. Population moments, moment-ratio diagrams and separation conditions of mixture and two-component product models were studied. New families of mixture of quantile models as well as estimation based on censored MLE for mixture models were developed. Likewise, moment and MLE procedures for estimating the Box-Cox transformation parameter were derived. Results based on simulation experiments indicated that regional MLE may be beneficial in estimating flood quantiles at a given site as compared to at site estimates or estimates derived by alternative least square methods, under the assumption of a reliable regional parametric structure. However, as the parametric structure becomes unreliable, the benefits of regional MLE become less apparent. Likewise, in comparing regional MLE with generalized least squares methods based on observed flood data, results indicate that both methods perform about the same. (USGS)

Although many hydrological characteristics are the same for all arid zones, tropical Africa presents particular characteristics: well-defined rainy season, simple storm intensity patterns, high temperatures, impervious crust on many soils reducing infiltration, large part of the soil without cultivation, and few and very sparse hydrometric networks. This situation dictates certain approaches to estimating the 10-yr flood and mean annual discharge and its distribution for small and relatively small basins. In the absence of network data, precipitation series are used as a statistical basis combined with the transformation of precipitation into discharges analyzed in representative basins and transposed for unknown basins. Global models are used for the heterogeneity problems. For the 10-yr flood, the approach is deterministic and uses broadly the unit hydrograph, the flood flow being for most cases surface runoff. The product function often is simple, the storm pattern being generally the same and the precipitation depth by far the most important factor in runoff depth. In the past, empirical curves have been established giving the runoff coefficient for the 10-yr precipitation from the basin area, slope global index, and infiltrability class. For very small basins, the curves (revised in 1986) give the runoff coefficient for daily precipitation from 70 mm and 100 mm depth. A catalog of quantitative infiltrability of

surfaces makes the infiltrability classification more reliable. The transfer function corresponds to the unit hydrograph. For the transposition, empirical curves give the rise time, base time, and the peak coefficient in relation to slope area secondary factors using a checklist. The large number of representative basins permits the cautious use of multiple regression. This methodology, which presents some limitations (hydrographic degeneration), will be improved by the use of the catalog and of a checklist of the factors neglected by the regressions. The methodology can be employed for the transposition of statistical distribution of annual runoff depths. (See also W91-02288) (Author's abstract)

Descriptors: *Africa, *Arid lands, *Flood forecasting, *Flood peak, *Floods, *Sahel, *Semiarid lands, *Ungaged streams, Estimating equations, Fictitious basin concept, Infiltration, Rainfall-runoff relationships, Unit hydrographs.

Practical rules were developed for the estimation of peak discharge of the 10-yr flood on ungauged basins under 10 sq km in the Sahel, West Africa. This work was carried out on 29 representative Sahelian catchments. Problems of flood estimation in the Sahel are presented and original aspects of the procedure are pointed out. The estimation of the 10 yr flood uses observed data, the runoff coefficient, and the unit hydrograph parameters. The use of the fictitious basin concept was employed for the survey of the whole variation field of the hydrograph characteristics in relation to four main factors: area, 10-yr rainfall depth, slope, and infiltrability. The method can be employed in conjunction with a questionnaire to take into account possible extreme values of other runoff factors of possible significant influence. Sahelian floods are caused by heavy convective rainfall displaying some homogeneity at the small watershed scale. For that reason, and because there is no groundwater flow, the unit hydrograph (UH) is well suited to modeling of Sahelian floods. Three UH identifying methods were compared: the Nash UH, a recursive least square (RLS) identification of an autoregressive model with exogenous input (ARX), and the so-called DPFT (Difference Premiere de la Fonction de Transfert), an iterative deconvolution process. The comparison was based on data from two watersheds of less than 20 sq km and it permits an examination of the validity of the UH concept as applied to the Sahelian floods. The influence of the calibration sample and of the analytic formulation of the production function on the coefficients of the linear transfer function also were studied. In this regard, the DPFT seems to be the most objective of the methods studied. According to the methods used, the UH which were identified were obviously different, but the essential problem remains that of selecting the analytical expression of the production function, especially when the rains present an important spatial variability. Analysis of the speed of propagation of flood waves was perfected to set up a model of flood propagation for the River Niger. The analytical methodology developed has led to numerous applications, now in almost daily use. These include: anticipating flow, simulation, real-time management of developments, and height-discharge transformation (non bi-univocal stations). The development of this methodology is described here and each application of the analysis is present in the form of a concrete example. These examples include: a model of the Niger flood propagation in the Koulikoro/Kemacina reach; reconstruction of the Gambia River flow at Kouncy; anticipated management flow for the OMVS Management's communal installations at Manantali Dam; and graduation at Boghe station on the Senegal River. A brief summary of the hydraulic elements used to develop the methodology and a diagrammatic approach to it based on St. Venant's equation are presented as well. Descriptors: *Hydrologic models, *Model studies, *Rainfall-runoff relationships, *Water supply development, Burkina Faso, Computer programs, Management planning, Mathematical models, Tunisia.

Operational versions are described of two conceptual and deterministic models for the rainfall-runoff relationship: CREC and MODGLO. These models are intended to serve as real tools for water project managers. The informatics structure as it applies to microcomputers is emphasized, with a minimum of theoretical discussion. For each model, the productional and transfer functions are discussed and methods for determing parameter values are briefly considered. Programming examples are given. Entries are available for 10-day periods, months, and/or years in the form of tables and graphs to permit the comparison of computed and observed data. Applications are presented for a catchment in

Tunisia and two in Burkina Faso. (See also W91-02288) (Author's abstract)

Determination of design and construction floods is critical in the choice of spillway, outlet, and reservoir design, operation, and management, and maintenance of any hydrosystem. Operation security providing a reliable flood warning system and the ability to predict high floods require that valid assumptions be made in the development and application of stochastic and deterministic models for prediction and forecasting. The need for models in the planning, design, operation, and management of water resources systems is discussed. General considerations on river basin models are delineated and some models that have been applied to the River Nile and equatorial lakes in Africa are evaluated. Limitations were identified in the Sacramento Model, Stanford Watershed Model IV, Queen's University Forecasting Model, and Streamflow Synthesis and Reservoir Regulation Model. A real-time runoff forecasting technique was developed that incorporates the soil-plant-atmospheric continuum as a way of facilitating a more realistic prediction and forecasting for use in Africa and elsewhere. The model is basically a conceptual water balance model that eliminates the problems encountered by other models through the complex soil-plant-atmosphere continuum. The model has been implemented successfully for Big Creek River basin in eastern Ontario and implementation is now in progress for the river basins Nile and Rufiji (northern and eastern Africa), Zambezi (southern Africa), and Niger (western Africa). The Niger and Senegal rivers are extremely important sources of water for the semi-arid regions in West Africa, and a knowledge of their characteristics and the potential for control is vital for Mali, Senegal, and Mauritania in particular. These rivers exhibit extremely variable flows on seasonal and longer-term scales because rainfall in the headwaters, which provide the areas of runoff, is highly seasonal and variable. The river flows reflect the rainfall and contribute a source of water to arid areas that varies between intense flooding and extreme low flows. The seasonal inundation of riverine floodplains forms the basis of traditional land use, but reservoir storage offers the maintenance of dry season flows and thus the supply of water for hydroelectric power production, irrigation, and improved navigation conditions. The combination of these objectives, achieved by using storage projects for the maintenance of an artificial flood is illustrated by reservoir operation in different years. Descriptors: *Stream discharge, *Stream profiles, *Streams, *Water chemistry, *Water temperature, Ammonium, Conductivity, Germany, Organic matter, Phosphates, Phosphorus, Seasonal variation.

Temperature, discharge, and chemical parameters were studied in the upper reach of a Black Forest stream (Germany) over a three-year period. Additionally, investigations of the upstream tributaries and of downstream sites were conducted at some occasions. While monthly and annual means of water temperature exhibited only little year-to-year variations, average annual discharge differed considerably. Total suspended organic matter was correlated to total suspended solids and discharge, orthophosphate and ammonium to temperature. Phosphorus was the only nutrient with a strong seasonal dynamic. Cumulative surface runoff of the upstream tributaries was inversely correlated to total discharge at the gauging station. Concentrations of Ca(2+) and Mg(2+) and accordingly, specific conductivity, increased in the longitudinal course of the stream, due to tributaries originating in the adjacent shell limestone and red marl formations. During annual flooding of the Amazonian valley the sediment load of the river, resulting fron Andean erosion, is deposited into the river floo basin. In Peruvian Amazonia, the successiona vegetation on both the Putumayo River alluvia floodplain and the Madre de Dios River basin hav been described; there is little available informatio concerning the forested areas of these wetlands. I the alluvial floodplain of the Ucayali River valley a succession is evident on the convex banks. O the episodically flooded ridges, graminaean, shrub by, and arborescent pioneer stages develop. In th swales, which are flooded annually, a graminaea stage preceeds two shrubby pioneer stages. In ger eral, vegetation, growth, and survival is sensitiv to flood time, with the Moraceae evident as th most important pioneer species. In general, a rel tionship between textural soil features and vegeta tion development was apparent only at the begi ning of the succession. Species distribution profile indicated four degrees of perturbation: occasion flooding, annual short flooding, annual long floo ing, and annual vegetation submersion. If suc changes persist, both the structural and florist features of the flooded forests could be modifie potentially diminishing their future species divers ty. (D'Agostino-PTT)

The bald cypress and water tupelo are the predominant timber species in many flooded areas in the forested wetlands of the southeastern United States. Due to the projected trends of delta subsidence, sea-level rise, and human flood control measures, these species will be exposed to longer flooding durations. Information on their growth response to these changing conditions is necessary to ensure their future survival. The influence of flooding on mixed stands of bald cypress (Taxodium distichum) and water tupelo (Nyssa aquatica) was investigated using two second-growth stands, one continuously flooded (CF) and the other seasonally flooded (SF). In the SF stand, the large bald-cypress was fast-growing, whereas, the water tupelo exhibited high mortality rates. In contrast, bald-cypress growth was slower in the CF stands, and the water tupelo rate was slightly faster. As a result, although the water tupelo lost basal area in the SF stand, it was more competitive against the bald-cypress in the CF stand. While a mixture of the two species will potentially be retained under conditions of constant flooding, seasonal flooding may eliminate the water tupelo from the site. (D'Agostino-PTT)

Recent observations in Mississippi River swamp forests indicate that the combined adverse conditions of anaerobiosis, from soil flooding, and increased salinity may potentially eliminate flood tolerant tree species that are salt-sensitive. A comparison of Taxodium distichum and Nyssa aquatica seedling survival demonstrated that anaerobiosis alone resulted in a greater reduction of carbon assimilation rates in T. distichum than in N. aquatica. In a similar response, the combined stress of anaerobiosis and salinity resulted in carbon assimilation rates which decreased 46% in T. distichum and 24% in N. aquatica. Based on height growth, both species appear to have the same level of sensitivity, namely a 56% height growth reduction in T. distichum and a 54% height growth reduction in N. aquatica. Both species are also salt-sensitive. From the combined data, it was concluded that both seedling survival and regeneration will be adversly affected in coastal forests where salt water intrusion frequently occurs. (D'Agostino-PTT)

An algorithm is presented for tracing the path of steepest descent from a given starting point on a terrain model defined by a triangulated irregular network. This algorithm is then extended to solve several problems. The flow patterns for a site are generated by tracing flow paths from a large number of starting points. The approximate stream network or channel network is found by tracing the channels upstream from pits or exit points. Once the stream network is found, the source areas or contributing areas for each of the sections of the stream are delineated. The source areas are then used to delineate the watersheds of selected nodes in the channel network. The watersheds of any of the delimiting nodes of the two models tested could be computed and drawn in 1-2 sec or less. The algorithms described are useful for tracing the path of drainage over the terrain surface from points of origin, in the design of site grading, and for generating the geometry required for finite element modeling of surface water flow. MISSISSIPPI RIVER-GULF OUTLET, LOUISIANA: FIELD DATA REPORT.
Army Engineer Waterways Experiment Station, Vicksburg, MS. Hydraulics Lab.
T. L. Fagerburg.
Available from the National Technical Information Service, Springfield, VA 22161. Technical Report HL-90-7, August 1990. 172 p, 54 plates, 70 tab.

Descriptors: *Hydrologic properties, *Louisiana, *Mississippi River, *Shoals, *Suspended sediments, Canals, Flow velocity, Lake Borgne, River flow, Salinity, Water level.

Water levels, current speeds and directions, salinities, and suspended sediment concentrations were measured in the Mississippi River-Gulf Outlet Canal (MRGO), New Orleans, LA, in October and November 1988. The prototype data were collected as part of a study to incorporate these data in a numerical model for determination of shoaling rates. The following observations were made: (1) there appears to be a slight decrease in the maximum range of water surface elevation (0.12 ft) from the Chandeleur Sound location to the upper reaches of Lake Borgne; (2) the maximum velocities observed during the surveys occurred at the strength of flood periods. The maximum observed velocity was 3.6 ft/sec at one station on 26 October; (3) suspended sediment concentrations within the MRGO channel were found to be generally greater near the bottom during the strength of flood periods. The suspended sediment concentrations within Lake Borgne were high (106 to 283 mg/L) during windy periods and low (5 to 64 mg/L) during calm periods; (4) salinity values indicated that the lower portion of the MRGO could be described as being partly mixed to well mixed, while the upper portions could be described as being generally well mixed; and (5) correlation of suspended sediment data with satellite data were not successful due to cloud cover during the periods data were obtained. Descriptors: *Acid rain, *Forest hydrology, *Geochemistry, *Ion transport, *Soil chemistry, *Solute transport, *Surface-groundwater relations, *Wales, *Weathering, Aluminum, Conifers, Fish populations, Groundwater movement, Hydrogen ion concentration, Perched water table, Potable water, Slopes, Soil water, Storm runoff, Streamflow, Water quality.

Streams draining coniferous forests are often loaded with solutes such as hydrogen ion, sulfate, nitrate and aluminum. As a result, fish populations can be reduced and water quality may fall below recommended potable standards. The transport of ions into water-courses is governed by the movement of water. Within most temperate and tropical areas the stream discharge and chemistry, during periods of rapid runoff, is dominated by the exfiltration of water and solutes from stream-side soils. The movement of water to stream-side or riparian areas remains, however, an enigma. Two analytical techniques, the free-surface method and tangent-continuity method, are applied to hydrological properties monitored on a steep coniferous hillslope, during a selected storm event. Comparison of the ionic concentrations of waters within each component of the hydrological systems, is used to verify the hydrological analysis. Perched water-tables developed within the basal zones of the O/Ah and Eag soil horizons of the steep podzolic hillslopes, during all major storm events. Most of the rapid response within the riparian zone could be explained by lateral flow in these near-surface soil horizons, particularly in the saturated basal zones. This pathway is corroborated by the similarity of riparian zone and near-surface (or topsoil) chemistries. Relatively low concentrations of monomeric aluminum and relatively high concentrations of chloride, sodium and hydrogen ion were observed within these zones, compared with the subsoil (Bsl and B/C) horizons. With respect to both discharge and sediment load, the flood plain environment is one of increasing geomorphological attention. A two-dimensional horizontal finite element numerical model (RMA-2) was applied to a 24-km river channel-flood plain reach in West Germany. Initial results indicate that finite element schemes may successfully estimate the depth and lateral extent of inundation in large-scale flood plain applications. The model was found to be robust against field uncertainty in flood plain roughness estimation. Stability of solutions for wetting and drying of large areas was greatly improved by use of the 'marsh' element option. Potentially, the resulting detailed velocity vector distributions and identification of inundation zones throughout storm events could provide an insight into the present day sedimentary environment on the flood plain. Journal of Geophysical Research (C) Oceans JGRCEY, Vol. 95, No. 9, p 16,097-16,109, September 15, 1990. 15 fig, 1 tab, 29 ref. National Water Research Institute Grant No. NKW405-8-2258/01-SE.

Descriptors: *Lake Ontario, *Niagara River, *Water temperature, Advection, Great Lakes, Seasonal variation, Thermal stratification, Tidal hydraulics, Upwelling, Water circulation.

Temperature and velocity data are used to describe the Niagara River discharge into Lake Ontario between April and November 1982. The Niagara River discharge (7000 cu m/s) is usually slightly warmer and therefore less dense than the ambient lake surface water. The density difference varies throughout the year, with the largest density differences being measured in October. Near the river mouth, where the fluid speeds are roughly 1 m/s, the plume is vertically homogeneous. Here advective forces dominate the momentum balance, even in the presence of strong wind forcing. Approximately 5 km off shore, the plume separates from the lake bottom as the water depth increases and buoyancy forces become important. At the offshore boundary of the plume, advection, Coriolis force, buoyancy, and wind stress are all important. The Coriolis effect acts to turn the plume anticyclonically and form a right bounded coastal current with speeds of 0.1-0.2 m/s. Strong upwelling favorable winds force the buoyant plume to spread offshore, thinning the plume as it spreads. Eventually, the plume water is mixed with the lake water by the wind. Strong downwelling-favorable winds concentrate the plume into a narrow and deep coastal current traveling downwind with the coast on its right. Thus, exchange between the plume and the lake is enhanced by upwelling-favorable winds and inhibited by downwelling-favorable winds. (Author's abstract)

LOW FLOW ESTIMATION BASED ON RIVER RECESSION RATE.
Clyde River Purification Board, East Kilbride (Scotland).
J. C. Curran.
Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 4, No. 4, p 350-355, August 1990. 6 fig, 11 ref, 2 append.

Descriptors: *Data interpretation, *Forecasting, *Low flow, *Recession, *River flow, *Water pollution control, River mechanics, Statistical analysis.

Successful pollution control in a river is fundamentally based on a reliable knowledge of the flow available for dilution of the polluting discharges. Often there may be no available gaging records within a catchment or subcatchment, and it may be necessary to resort to an estimation procedure. Low flow can be predicted through the consideration of: (1) a recession period and its relation to rainfall, and (2) a recession rate and its relation to local soil types. The principal advantages of the recession method are that greater resolution for small catchments is available using the land capability maps compared to the base flow indicator map. Afforestation, influence of tributaries, and catchment storage can all be incorporated explicitly in this estimation procedure. (Lantz-PTT)

EVALUATION OF REGIONAL FLOOD FREQUENCY ANALYSIS WITH A REGION OF INFLUENCE APPROACH.
Manitoba Univ., Winnipeg. Dept. of Civil Engineering.
D. H. Burn.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2257-2265, October 1990. 4 fig, 1 tab, 11 ref.

Descriptors: *Flood forecasting, *Flood frequency, *Gaging stations, *Network design, *Regional floods, Drainage patterns, Error analysis, Estimating, Monte Carlo method, Statistical methods.

The region of influence (ROI) approach allows for a unique set of gauging stations to be used in the at-site estimation of extremes for every station in a collection of gaging stations. The starting point for the ROI approach to regionalization is the selection of a distance metric defining the closeness of each station to every other station. Attributes based on physical features of the contributing drainage area for a station or on statistical measures of the data record at each site can be incorporated into the distance metric. The selection of a set of attributes for inclusion in the distance metric from the array of possible attributes can be accomplished using a screening process to identify those attributes that are most indicative of similarity in extreme flow behavior. Threshold values define a cutoff for the inclusion of stations into an ROI for a site. Finally, a weighting function reflecting the relative closeness to the site of each station in a site's ROI is determined. Through a Monte Carlo experiment, the ROI approach provides improved at-site estimates of extreme flow quantiles in terms of network average root mean squared error and comparable results for bias. The method is further shown to have attractive features for estimating extremes for unusual sites in a network of gauging stations. (Brunone-PTT)

RELIABILITY ESTIMATION IN MODELING WATERSHED RUNOFF WITH UNCERTAINTIES.
Rutgers - The State Univ., Piscataway, NJ. Dept. of Civil and Environmental Engineering.
C. S. Melching, B. C. Yen, and H. G. Wenzel.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2275-2286, October 1990. 5 fig, 4 tab, 34 ref. Union Carbide Agricultural Company contract No. 81065-C.

Descriptors: *Hydrologic models, *Model studies, *Rainfall-runoff relationships, *Runoff, *Uncertainty, *Watersheds, Discharge capacity, Mathematical models, Probability distribution, Seasonal variation, Vermilion River.

The reliability of simulation results produced by watershed runoff models is a function of uncertainties in nature, data, model parameters, and model structure. A cumulative distribution function (CDF) and/or a probability density function of the magnitude of the predicted peak discharge accounting for the various uncertainties from different contributing factors provides a framework for using a reliability analysis method (such as first-order second-moment techniques or Monte Carlo simulation) to evaluate the combined effect of the uncertainties on the reliability of output hydrographs from hydrologic models. The peak discharge probability for the Vermilion River watershed in Illinois using the HEC-1 watershed model yields stochastic output due to the uncertainties in the basic variables of the model. The CDF of the estimation provides a visual means of assessing the estimation reliability. In the Vermilion River watershed model, results indicated that prediction of runoff resulting from non-summer rainstorms is more reliable than that for summer storms; the major contributors to unreliability of the model predictions are the initial loss and continuing loss rate parameters in HEC-1; and, hydrograph parameters and model correction factors contribute relatively little to prediction uncertainty. The study of the reliability of predictions from watershed models provides useful information on the stochastic nature of output from deterministic models subject to uncertainties and identifies the relative contribution of the various uncertainties to unreliability of model predictions. SPATIAL UNIFORMITY OF POWER AND THE ALTITUDINAL GEOMETRY OF RIVER NETWORKS.
Massachusetts Inst. of Tech., Cambridge. Ralph M. Parsons Lab.
V. Kapoor.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2303-2310, October 1990. 2 fig, 3 tab, 18 ref. Army Research Office Grant 26220-GS.

Descriptors: *Entropy, *Flow rates, *Geomorphology, *Model studies, *River mechanics, *River systems, *Scale factors, Climates, Mathematical models, River flow.

River networks are hypothesized to adjust their geometries in the altitudinal space to achieve a state of maximum spatial uniformity of power. A model developed to study the spatial variability of power shows that the notion of uniformity is linked to both minimum variance and maximum information theoretic entropy. The hypothesis relates the scaling exponent of link heights to the scaling exponents of instantaneous flows and predicts the superiority of the self-similar model over alternative models of link heights in channel networks. Self-similar models enable link power to be distributed with greater spatial uniformity than it is in the alternative models. The ability of the self-similar link height model to distribute power more uniformly in space should be tested for basins from different climatic regions for which both geomorphic data and flow data are available. WIDTH AND DEPTH OF SELF-FORMED STRAIGHT GRAVEL RIVERS WITH BANK VEGETATION.
Tokyo Inst. of Tech. (Japan). Dept. of Civil Engineering.
S. Ikeda, and N. Izumi.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2353-2364, October 1990. 14 fig, 20 ref, append. Ministry of Education and Culture of Japan Grant No. 01550398.

Descriptors: *Alluvial channels, *Channel morphology, *Gravel rivers, *Riparian vegetation, *River mechanics, *Vegetation effects, Flow velocity, Hydrologic models, River systems, Shear stress, Stream banks.

The influence of bank vegetation on the stable channel cross-sectional geometry of stable, straight gravel rivers is studied theoretically. Singular perturbation and matched asymptotic expansion techniques are employed to derive the lateral distribution of depth-averaged fluid velocity and the bed shear stress. A condition of sediment incipient motion is imposed at the junctions of the bed and the banks to derive the stable depth, and a formula for resistance to flow is used to obtain the stable width. The theory reveals that a thicker vegetation yields a larger depth and a smaller width. Increasing discharge increases the effect of vegetation. The analysis agrees reasonably well with available field data in natural gravel rivers in Colorado and England. (Author's abstract)

INCORPORATING HILLSLOPE EFFECTS INTO THE GEOMORPHOLOGIC INSTANTANEOUS UNIT HYDROGRAPH.
CH2M/Hill, Reston, VA.
L. D. Van der Tak, and R. L. Bras.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2393-2400, October 1990. 4 fig, 18 ref, append. National Science Foundation Grant 8513556-ECE.

Descriptors: *Geomorphology, *Hydrograph analysis, *Rainfall-runoff relationships, *Slopes, *Unit hydrographs, Discharge capacity, Drainage density, Flow rates, Probability distribution, Statistical analysis.

Use of gamma distributions of stream holding times, rather than the traditional exponential distribution, results in geomorphologic instantaneous unit hydrograph (GIUHs) that better fit data-based IUHs. In this paper, hillslope effects are incorporated into the gamma GIUH (GGIUH) model by assuming that the hillslope travel distance in an area of a given order is approximated by the inverse of twice the local drainage density and introducing a hillslope velocity term. A method of moments fitting procedure is used to estimate the channel and hillslope velocity terms in the GGIUH model from the moments of rainfall input and basin discharge output. Results showed that hillslope velocities are 2 orders of magnitude smaller than channel velocities. The values found for the latter are reasonable given the range of values found in the literature for channel velocities. Similarly, the hillslope velocity term found by the method of moments procedure matches macropore velocities reported in the literature. (Brunone-PTT)

PREDICTING RUNOFF FROM RANGELAND CATCHMENTS: A COMPARISON OF TWO MODELS.
Agricultural Research Service, Boise, ID. Northwest Watershed Research Center.
B. P. Wilcox, W. J. Rawls, D. L. Brakensiek, and J. R. Wight.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2401-2410, October 1990. 6 fig, 4 tab, 37 ref.

Descriptors: *Agricultural watersheds, *Hydrologic models, *Land use, *Model studies, *Prediction, *Rainfall-runoff relationships, *Runoff, *Runoff forecasting, *Watersheds, Comparison studies, Infiltration, Land management, Mathematical models, Parameterization, Resource management.

Two different hydrology models, both designed to predict runoff from ungaged rural catchments, were compared. One model is the commonly used and conceptually simple Soil Conservation Service curve number method. The other model is a process oriented model based on the Green and Ampt equation. The Green and Ampt model employs newly developed techniques for parameterizing the Green and Ampt equation based on readily available soil and vegetation information. Annual, monthly and daily predicted runoff were compared to observed on six uncalibrated rangeland catchments located in Texas, Oklahoma, Arizona, Nebraska and Idaho. Model parameterization was

based strictly on individual catchment characteristics. No model calibration was performed. Results indicate that the Green and Ampt model a potentially useful tool for predicting runoff. These results are important because they demonstrate the utility of complex physically based models as management tools for predicting land use impacts to runoff and infiltration. (Author's abstract)

ISLAND BIOGEOGRAPHICAL THEORY: CAN IT BE USED TO PREDICT LOTIC RECOVERY RATES.
Austin Peay State Univ., Clarksville, TN. Center for Field Biology.
J. A. Gore, and A. M. Milner.
Environmental Management EMNGDC, Vol. 14, No. 5, p 737-753, 1990. 4 fig, 1 tab, 135 ref.

Descriptors: *Biogeography, *Ecological effects, *Habitat restoration, *Lotic environment, *Model studies, *Stream biota, Classification, Mathematical analysis, Species diversity, Succession, Theoretical analysis.

Classic island biogeographic theory predicts that equilibrium will be reached when immigration and extinction rates are equal. These rates are modified by the number of species in a source area, the number of intermediate islands, the distance to a recipient island, and the size of the intermediate islands. This general model has been variously modified and proposed to be a stochastic process with minimal competitive interaction or heavily deterministic. Because disturbance frequency, severity, and intensity vary in their effect on community dynamics, disturbance levels should first be defined before evaluating the applicability of island biogeographical theory. A classification system is suggested consisting of four disturbance level based on recovery patterns. Level 1 disturbances completely destroy communities with no upstream or downstream sources of colonizers. Level 2 disturbances destroy the communities but leave upstream and downstream colonization sources. Level 3 disturbances result in reduction of species abundance and diversity along a stream reach. Level 4 disturbances result in reduction of abundance and diversity in discrete patches. Island biogeographical models seem appropriate to recovery by secondary processes after level 3 and 4 disturbances, where competition may be an important organizing factor, while models of numerical abundance and resource tracking are probably of better use where community development is by primary succession. Nonlinearities of bed transients of finite height have been documented through numerical modeling using finite difference (F-D) schemes. The numerical characteristics of two explicit F-D schemes, namely: de Vries's pseudoviscosity modified-Lax and Fromm's zero-average-phase-error schemes were used as a starting point. The performance of de Vries's scheme depends primarily on the relationship of the pseudoviscosity term to the bed Courant number selected and the spatial resolution used to discretize the bed wave, whereas the performance of Fromm's scheme depends on the bed Courant number chosen for the simulation. The optimal choice of these numerical parameters is a function of the bed wave height, the wave shape, and the Peclet and Froude numbers. These schemes were used in numerical simulations to determine the nonlinear behavior of a sinusoidal-shaped bed transient of finite height. The simulated motion of the bed were compared with that obtained by (linear small-amplitude) analytical methods; correction factors for both effective bed wave celerity and attenuation were incorporated as functions of the dimensionless wave height, the Peclet and Froude numbers. Even where there is very little diffusion present in the physical system, good results can be achieved if the viscosity term is chosen carefully. Convergence is easier to achieve when the Froude number and the dimensionless bed wave amplitude are small, and when the Peclet number is large. In most of the cases tested, the developed equations provided a good representation of the governing equations. (Author's abstract)

RESISTANCE TO FLOW IN STEEP ROUGH STREAMS.
Universidad de Los Andes, Merida (Venezuela). Dept. of Civil Engineering.
J. Aguirre-Pe, and R. Fuentes.
Journal of Hydraulic Engineering (ASCE) JHEND8, Vol. 116, No. 11, p 1374-1387, November 1990. 7 fig, 2 tab, 33 ref. Council for the Development of Sciences, Humanities and Technology (CDCHT) of the Universidad de Los Andes Grant I-204.

Descriptors: *Flow resistance, *Hydraulic roughness, *Mountain streams, *Open-channel flow, Boundary layers, Chezy equation, Darcy-Weisbach equation, Flow velocity, Flumes, Turbulent flow.

Flow resistance and velocity profiles associated with flow in open channels with small-scale roughness is customarily described in terms of boundary-layer theory. A theory of resistance to flow in steep, rough streams was developed that takes into account the existence of a highly turbulent wake zone near the bed of a very rough boundary. Two zones were identified in the field. The first one, close to the top of the bed, contains overlapping wakes generated by protruding roughness elements. In the second zone, located above the first one, the velocity distribution is described in terms of a logarithmic profile. Flume data were used to check the validity of this formulation. The compound velocity profile allows for equations to obtain Darcy-Weisbach and Chezy factors. The proposed approach is compared with the results of four previous theories using data obtained from several mountain rivers. Although flow in actual mountain rivers is more complicated than the idealized case treated in the study, the formulation provides equations that allow accurate prediction of flow resistance with a mean error of plus-or-minus 15%. Journal of Hydraulic Engineering (ASCE) JHEND8, Vol. 116, No. 11, p 1403-1414, November 1990. 2 fig, 6 tab, 30 ref. Fondo Nacional de Ciencia y Tecnologia de Chile, Proyecto FONDECYT 516/1989; Colorado Agricultural Experiment Station Project N. 645.

Descriptors: *Model studies, *Regression analysis, *Streamflow data, *Streamflow forecasting, *Time series analysis, Annual distribution, Computer models, Simulation analysis, Statistical analysis.

Since hydrologic time series in general, and streamflow series, in particular, are dependent and not normally distributed, use of the classical auto

egressive and moving average models to represent such series requires transformation of the original series into a normal distribution before applying the model. On the other hand, gamma-autoregressive (GAR) models assume that the underlying series is dependent with a gamma marginal distribution and the models do not require variable transformation. However, the models require the estimation of certain statistics generally leading to biased estimates of the model parameters. A procedure has been developed for bias correction, based on computer simulation studies, applicable for estimating parameters of GAR(1) models. Applications of the proposed procedure was made to annual streamflow series of several rivers. The GAR(1) model, when used in conjunction with the proposed estimation procedure, is an attractive alternative for synthetic streamflow simulation, is simple to use, and does not require any transformation of the original data. Descriptors: *Bed load, *Channel morphology, *Flow models, *Hydraulic models, *Model studies, *Particle size, *Sedimentary structures, *Temperature effects, Dunes, Flow velocity, Flumes, Plane flow, Ripple marks, River beds, Sand, Sedimentation, Water temperature.

Reynolds-Froude scale modeling using hot-water flows to model cold-water flows was applied to the study of unidirectional-flow bed configurations in a large, thermally-insulated laboratory flume. Three different water temperatures, ranging from 14 to 75 C, provided three different scale ratios, from 1.1 to 2.3. Effective sand sizes, scaled to 10 C water, were about 0.12 mm, 0.18 mm, and 0.28 mm. Relative to 10 C water, use of hot water multiplied the effective flow depth and all flume dimensions by factors of up to 2.3, the flow velocity by factors of up to 1.5, and the water discharge by factors of up to 8. The effective dimensions of the flume, scaled to 10 C water temperature, ranged up to over 26 m long and 2 m wide, with a flow depth of up to 0.5 m. In the coarser sand sizes (0.17-0.26 mm), three bed phases were observed: ripples, dunes, and upper-regime plane bed. Dunes tended to be two-dimensional (crests straight and continuous) at low flow velocities and three-dimensional (crests sinuous and discontinuous) at relatively high flow velocities, except that at flow velocities transitional between ripples and dunes the bed showed a complex intermingling of irregular larger dunelike bed forms and smaller irregular ripples. In the dune range, ripples were prominently superimposed at relatively low flow velocities but nearly absent at relatively high flow velocities. Existing data on bed states have not yet been thoroughly exploited to reveal relationships among the various bed phases. Therefore, data from 39 flume studies that report equilibrium bed configuration as well as water temperature, flow depth, flow velocity, and sediment size were used to develop the best approximation to the relationships among bed phases (ripples, dunes, lower-regime plane bed, upper-regime plane bed, and antidunes) produced by flows of water over loose sediments. A three-axis graph with dimensionless measures of mean flow depth, mean flow velocity, and sediment size along the axes was used. The relationships were illustrated as a series of depth-velocity sections and velocity-size sections through the dimensionless diagram. Boundaries between stability fields of the bed phases were drawn as smooth surfaces that minimize misplacement of data points. A large subset of the data, for which reliable values of bed shear stress are reported, was used to represent the stability relationships of the bed phases in a graph of dimensionless boundary shear stress against dimensionless sediment size. The graph shows substantial overlapping of the fields for dunes, upper plane bed, and antidunes owing to the decrease in bed shear stress in the transition from dunes to plane bed with increasing flow velocity. The topology of bed-phase boundaries was guided by the relationships shown in the dimensionless depth-velocity-size diagram. (See also W91-02935 and W91-02927) (Author's abstract)

Understanding of the mechanics of temperature-related changes in sediment transport is still rudimentary. A change in bed configuration caused by a change in water temperature without any change in flow and sediment variables in a unidirectional flow was analyzed in the context of a dimensionless depth-velocity-size diagram. Bed states that differ only in water temperature are termed temperature-related states. These are attainable from any given state solely by a change in water temperature. Such a set of bed states forms a curve in the dimensionless depth-velocity-size diagram. This curve, a straight line in a log-log-log plot, is termed a temperature-change line. To predict the change in bed state consequent upon a change in water temperature alone, one finds the temperature-related state lying along the temperature-change line passing through the original bed state in the dimensionless depth-velocity-size diagram. Three examples from the literature were analyzed in this way to show how such changes in bed configuration can be put into the context of existing stability relationships among the various bed phases, without however addressing the general dynamical problem of why those relationships are as they are. The effect of the acceleration of gravity on the bed configuration was also examined from the standpoint of the dimensionless depth-velocity-size diagram. The results show that in a hypothetical open-channel water flow on Mars a given transition between two adjacent bed phases with increasing flow velocity (e.g., ripples to dunes) would take place at a lower velocity on Mars than on earth, by a factor of 0.74. Cave formation in the phreatic zone of limestone aquifers involves the widening of mechanically opened joints, fractures, and bedding planes by groundwater that is slightly undersaturated with respect to calcite. The mixing of two groundwaters of dissimilar salinities is one of many mechanisms proposed to explain calcite undersaturation in water descending within the phreatic zone. Spatial and temporal relations among intracratonic basins, karstic terrain, and continental glaciation suggest that Pleistocene glaciation may have initiated the discharge of saline waters from the margins of these basins. Glaciation-induced discharge of saline waters could result from the consolidation of sediments due to the overlying pressure of glacial ice, and flushing of underlying aquifers as a result of bottom melting in recharge areas of basin aquifers. The upward migration of basin-derived saline waters into near-surface aquifers would result in the mixing of saline waters with infiltrating glacial meltwater and meteoric water. The development of a vertically restricted zone of mixing of saline and fresh water in limestone aquifers would result in the dissolution of limestone; this mechanism could be responsible for the formation, or at least the initiation of, some caves and associated karst features in the midcontinent region. Hydrogeological properties of tills are highly dependent upon factors as grain-size distribution, compaction, orientation of particles, presence of fractures, and occurrence of sorted sediments. These factors are dependent upon the till forming processes. Lodgement tills formed under active, temperate sliding glaciers are usually compact, rather homogeneous, and in many cases they are fractured. Melt-out tills deposited in connection with stagnant ice are in most cases less dense, have a lower percentage of fine-grained particles, and a higher abundance of sorted sediment lenses. Flow tills, which are mainly formed by a secondary flow of supraglacial debris, are commonly very variable and may have a low content of fine-grained components, a low degree of compaction, and are often closely associated with sorted glaciofluvial sediments. Till genesis is in many cases difficult to interpret, and an objective description of all main characteristics of the till is important in hydrogeological studies. The lodgement till has a lower effective porosity than the melt-out and flow tills due to its finer grain sizes and higher compactness. The saturated hydraulic conductivity of the lodgement till is lower, and dependent upon the fracture pattern. In melt-out tills and flow tills the occurrence of well sorted sediments will in many cases control the hydraulic conductivity. In all till types the structural properties are most important for the saturated water flow. (Author's abstract)

There is a distinctive difference in hydraulic properties between the upper horizons of Scandinavian till soil and the deeper C-horizon. The hydraulic conductivity has been studied in different soil profile types, mainly podzolic variants. In the topsoil there are correlations from grain size and porosity to hydraulic conductivity. Both porosity and hydraulic conductivity are stratified with depth. Often high conductivity appears in the upper soil horizons decreasing with depth to low values at about one meter. This pattern varies with soil type. The soils vary with topographic location as does the groundwater level. Published data on hydraulic conductivity in the C-horizon of sandy-silty tills in Scandinavia covers a wide range, from about 5 x 10 to the minus ninth power m/s to 5 x ten to the minus fourth power m/s, with a mean of 3 x ten to the minus sixth power m/s. The correlation between porosity and hydraulic conductivity, as well as between mean grain size and hydraulic conductivity, is weak in the C-horizon. It is concluded that the sediment structure has a decisive influence on the hydraulic conductivity of till. A model of the relationship between particle orientation (in relation to water flow direction), the porosity in the pore-size interval of 30-95 micrometers, and the hydraulic conductivity suggests that if the particle orientation is near parallel to the flow, the porosity in the relevant interval has a greater impact on the hydraulic conductivity than if the orientation is transverse to the flow. SATURATED HYDRAULIC CONDUCTIVITY OF CLAYEY TILLS AND THE ROLE OF FRACTURES.
Technical Univ. of Denmark, Lyngby. Inst. for Teknisk Geologi.
J. Fredericia.
Nordic Hydrology NOHYBB, Vol. 21, No. 2, p 119-132, 1990. 2 fig, 51 ref. Danish National Council for Technology Grant No. 5.26.13.05.

Descriptors: *Denmark, *Fracture permeability, *Glacial sediments, *Groundwater movement, *Hydraulic conductivity, *Radioisotopes, *Till, Geologic fractures, Glaciohydrology, Porosity, Sediment sorting, Sedimentation.

The number of published hydraulic conductivities of clayey till in Denmark is still small, and more data is needed. Information concerning fracture systems in till is particularly important; these systems can be revealed by geological mapping of fracture distribution, spacing, and depth of occurrence. Controlled tracer tests can provide information concerning actual transport velocities and the importance of diffusion, and isotope studies can give the age of the porewater. In thick clayey till, tritium possesses possibilities as a fracture indicator because of diffusion. Existing data show a difference of 1-2 orders of magnitude in the vertical hydraulic conductivity between values from laboratory measurements and field measurements. Based on new data, field observations, and comparison with North American studies this lack of agreement is concluded to be primarily due to fractures in the till. Hydraulic tests with direct measurements in the aquitard, such as slug tests and pumping tests, can provide bulk hydraulic conductivities for different volumes. Hydrologic and chemical data are necessary to understand how effective a barrier clayey till is against migration of pollution. (Tappert-PTT)

Chemical transport in geologic media is known to be strongly influenced by spatial variations in hydraulic conductivity. Apparent longitudinal dispersivity data from a variety of hydrogeologic settings are assumed to represent a continuous hierarchy of log hydraulic conductivity fields with mutually uncorrelated increments, each field having its own exponential autocovariance, associated integral scale, and variance that increases as a power of scale. Such a hierarchy is shown theoretically to form a self-similar random field with homogeneous increments. Regardless of whether or not the underlying assumption is valid, one can justify interpreting the apparent dispersivities in a manner consistent with a recent quasi-linear theory of non-Fickian and Fickian dispersion in a homogenous media which supports the notion of a self-similar hierarchy a posteriori. The hierarchy is revealed to possess a semivariogram and a fractal dimension which can be viewed as a universal scaling rule, about which large deviations occur due to local influences, including the existence of discrete natural scales at which log hydraulic conductivity is statistically homogenous. As such homogeneity is at best a local phenomenon occurring intermittently over narrow bands of the scale spectrum, one must question the utility of associating medium properties with representative elementary volumes and relying on Fickian models of dispersion over more than relatively narrow scale intervals. Porous and fractured media appear to follow the same idealized scaling rule for both flow and transport, raising a question about the validity of many distinctions commonly drawn between such media. Finally, the data suggest that conditioning transport models through calibration against hydraulic measurements has the effect of filtering out large-scale models from the hierarchy. FLOW TO A HEATED BOREHOLE IN POROUS, THERMOELASTIC ROCK: ANALYSIS.
Sandia National Labs., Albuquerque, NM. Fluid Mechanics and Heat Transfer Div. I.
D. F. McTigue.
Water Resources Research WRERAQ, Vol. 26, No. 8, p 1763-1774, August 1990. 6 fig, 1 tab, 16 ref, append. United States DOE Contract No. DE-AC04-76DP00789.

Descriptors: *Boreholes, *Fluid flow, *Geohydrology, *Geothermal studies, *Groundwater movement, *Temperature effects, Diffusion, Heat flow, Mathematical analysis, Pore pressure, Porous media, Rock properties, Thermal conductivity.

Exact solutions are obtained for fluid flow induced by the heating of a borehole. The rock is modeled as a fluid-saturated, porous, thermoelastic medium. The temperature and pore pressure fields are governed by a pair of diffusion equations, which are coupled through a source term in the pressure equation proportional to the temperature rate. The pressure profile exhibits a maximum that grows in magnitude and propagates away from the borehole. For a constant heat flux applied as an instantaneous step, the fluid flux to the borehole takes a finite initial value, and decays monotonically. When the heat flux exhibits a finite rise time, the fluid flux is initially zero, rises to a maximum, and then decays. At late time, the inverse of the fluid flux is linear in ln(t); this observation can be ex

ploited to estimate the permeability and fluid diffusivity of low-permeability rock. Sample calculations for Westerly granite shows modest success. (Author's abstract)

COMPARISON OF DARCIAN FLOW IN CORRESPONDING FLAT AND FOLDED SURFACES.
Geological Survey, Denver, CO.
E. Weiss.
Water Resources Research WRERAQ, Vol. 26, No. 8, p 1775-1785, August 1990. 5 fig, 1 tab, 9 ref, append.

Descriptors: *Aquifer characteristics, *Darcys law, *Fluid flow, *Geohydrology, *Geologic formations, *Groundwater movement, *Model studies, Boundary conditions, Geologic control, Hydraulic conductivity, Hydraulic head.

Flat surfaces are frequently used as models of aquifers even though aquifers are folded and have a variation in hydraulic head along the vertical. To account for aquifer folds in groundwater flow models, the equation describing Darcian flow in a general surface is derived. The equation is used to calculate steady state hydraulic head distributions for corresponding folded and flat surfaces. Each flat surface has the same hydraulic conductivity distribution and boundary conditions as the corresponding folded surface. The folded surfaces have folds similar to the folds of selected aquifers and have folds that have much larger changes in slope. The largest difference in hydraulic head caused by all folding is only about 0.5% of the largest difference in hydraulic head across each surface. Hydraulic head distributions in surfaces composed of sinusoidal synclines and anticlines indicate that the effect of folds is not cumulative. Because of the smaller areal extent and the fact that the effect of a sequence of folds is not cumulative, the minor folds do not generate substantially larger hydraulic head differences than the major folds. RESPONSE OF THE WATER LEVEL IN A WELL TO EARTH TIDES AND ATMOSPHERIC LOADING UNDER UNCONFINED CONDITIONS.
Geological Survey, Menlo Park, CA.
A. Rojstaczer, and F. S. Riley.
Water Resources Research WRERAQ, Vol. 26, No. 8, p 1803-1817, August 1990. 8 fig, 3 tab, 22 ref.

Descriptors: *Aquifers, *Atmospheric pressure, Earth tides, *Geohydrology, *Groundwater level, *Groundwater movement, *Unconfined aquifers, *Wells, Confined aquifers, Hydraulic conductivity, Hydraulic head, Unsaturated zone.

The response of the water level in a well to earth tides and atmospheric loading under unconfined conditions can be explained if the water level is controlled by the aquifer response averaged over the saturated depth of the well. Because vertical averaging tends to diminish the influence of the water table, the response is qualitatively similar to the response of a well under partially confined conditions. When the influence of well bore storage can be ignored, the response to earth tides is strongly governed by a dimensionless aquifer frequency Q'u. The response to atmospheric loading is strongly governed by two dimensionless vertical flow parameters: a dimensionless unsaturated zone frequency R, and a dimensionless aquifer frequency Qu. The differences between Q'u and Qu are generally small for aquifers which are highly sensitive to earth tides. When Q'u and Qu are large, the response of the well to earth tides and atmospheric loading approaches the static response of the aquifer under confined conditions. At all values of Q'u and Qu, well response to earth tides and atmospheric loading is strongly influenced by water table drainage. When R is large relative to Qu, the response to atmospheric loading is strongly influenced by attenuation and phase lag of the pneumatic pressure signal in the unsaturated zone. The presence of partial penetration retards phase advance in well response to earth tides and atmospheric loading. When the theoretical response of a phreatic well to Earth tides and atmospheric loading is fit to the well response inferred from cross-spectral estimation, it is possible to obtain estimates of the pneumatic diffusivity of the unsaturated zone and the vertical hydraulic conductivity of the aquifer. CURIOUS BEHAVIOR OF A GROUNDWATER FLOW MODEL.
Butler Univ., Indianapolis, IN. Dept. of Mathematical Sciences.
J. P. Fink.
Water Resources Research WRERAQ, Vol. 26, No. 8, p 1833-1836, August 1990.

Descriptors: *Boundary conditions, *Flow models, *Groundwater movement, *Mathematical models, *Model studies, *Water table fluctuations, Capillary zone, Diffusion, Drawdown, Free surfaces, Unconfined aquifers.

In formulating mathematical models of unconfined groundwater flow, the nature of the transition zone between saturated and dry aquifer material has been handled in a variety of ways. The simple formulation obtained by assuming a free surface is not valid in many cases. A useful approach is to apply a capillarity correction term c to the free surface formulation. For sudden drawdown the problem has been expressed as an initial boundary value problem (IBVP). There are striking differences in the behavior of solutions to the IBVP which depend on the value of the capillarity correction term. For $c = 0$, the differential equation which reduces to the diffusion equation has a smoothing effect on the initial data. On the other hand, for $c > 0$ the differential equation preserves the discontinuity resulting from the incompatibility of the initial and boundary data. In physical terms, any initial fluctuations in the water table disappear almost immediately if $c = 0$ and persist indefinitely if $c > 0$. The properties exhibited by the IBVP suggest that it should be used with care. The diffusion equation which results when $c = 0$ should not be viewed as the proper limiting case when $c > 0$. The change in the highest order term makes the difference between a parabolic problem and a pseudoparabolic problem. (Tappert-PTT)

WATER-QUALITY CHARACTERISTICS OF THE COLUMBIA PLATEAU REGIONAL AQUIFER SYSTEM IN PARTS OF WASHINGTON, OREGON, AND IDAHO.
Geological Survey, Tacoma, WA. Water Resources Div.
W. C. Steinkampf.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 87-4242, 1989. 37p, 27 fig, 4 tab, 12 ref.

Descriptors: *Aquifer systems, *Columbia Plateau, *Regional Aquifer System Analysis, *Washington, *Water quality, Grande Ronde Basalt, Groundwater, Saddle Mountains Basalt, Wanapum Basalt, Water type.

Water quality data for the period 1982 through 1983 from about 350 wells in three Miocene basalt units in the Columbia Plateau regional aquifer system, Washington, show that the quality of groundwater generally is suitable for most uses. The dominant water type is calcium magnesium bicarbonate at shallow depths, and evolves toward sodium bicarbonate at depth. Calcium magnesium sulfate chloride type waters occur less commonly and are associated with shallow wells, the absence of a thick overburden, and agricultural land use. Dissolved-solids concentrations generally are less than 500 mg/L. Water in the Saddle Mountains unit has a mean dissolved-solids concentration of 488 mg/L. Nitrogen species and sulfate concentrations relate to overburden thickness and land use. Water in the Wanapum unit, below the Saddle Mountains unit, has a mean dissolved-solids concentration of 270 mg/L. High nitrogen concentrations (10 mg/L or greater) occur mostly in wells with depths less than 300 ft in areas with little or no overburden in the central part of the plateau. The Grande Ronde unit, below the Wanapum, has the lowest mean dissolved-solids concentrations, 230 mg/L, and nitrogen concentrations ar less than 2 mg/L. (USGS)

Descriptors: *Aquifers, *Groundwater, *Groundwater movement, *Memphis Aquifer, *Potentiometric level, *Tennessee, *Water level fluctuations, Groundwater recharge, Memphis Sand, Water resources data.

Recharge to the Memphis aquifer of Tertiary age is from precipitation on the outcrop, which forms a broad belt across western Tennessee, or by downward infiltration of water from the overlying fluvial deposits of Tertiary and Quaternary age and alluvium of Quaternary age. In the outcrop-recharge belts, where the Memphis aquifer is under water-table conditions, the potentiometric surface is complex and generally resembles the topography. To the west of the outcrop-recharge belt where the Memphis aquifer is confined, the potentiometric surface gently slopes westward, and the water moves slowly in that direction. A major cone of depression in the potentiometric surface in the Memphis area is the result of long-term (1986-present) pumping at municipal and industrial well fields. Water levels in the Memphis aquifer have declined at average rates ranging from less than 0.1 to 1.3 ft/year during the period 1928-85. The largest declines have been in the Memphis area where withdrawals averaged about 191 million gal/day in 1985. Near the center of the major cone of depression in the Memphis area water levels ceased to decline in about 1975, and the center of the cone essentially has stabilized. Away from the center of the cone, water levels are still declining at a low rate, and the cone is still expanding as a result of the long-term effects of pumping. (USGS)

GEOLOGY AND GROUND-WATER RESOURCES OF THE COCKFIELD FORMATION IN WESTERN TENNESSEE.
Geological Survey, Nashville, TN. Water Resources Div.
W. S. Parks, and J. K. Carmichael.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 88-4181, 1990. 17p, 2 pl, 5 fig, 4 tab, 21 ref.

Descriptors: *Aquifers, *Cockfield Formation, *Geology, *Groundwater availability, *Groundwater resources, *Tennessee, *Water quality, Aquifer characteristics, Cockfield Aquifer, Geologic formations, Groundwater movement, Groundwater recharge, Potentiometric level, Stratigraphy, Structural geology, Water level fluctuations, Water supply development.

The Cockfield Formation of the Claiborne Group of Tertiary age underlies approximately 4,000 sq mi in western Tennessee. The formation consists primarily of lenticular beds of very fine to coarse sand, silt, clay, and lignite. The Cockfield Formation has been extensively eroded, and the original thickness is preserved only in a few areas where the formation ranges from 235 to 270 ft in thickness. Recharge to the Cockfield aquifer is from precipitation on sparse outcrops or by downward infiltration of water from the overlying fluvial deposits of Tertiary and Quaternary age and alluvium of Quaternary age or, where present, the overlying Jackson Formation of Tertiary age. Data

from two observation wells indicate that water levels have risen at average rates of about 0.5 and 0.7 ft/year during the period 1980-85. Water from the Cockfield aquifer is a calcium bicarbonate type that contains low concentrations of most major constituents, and generally is suitable for most uses. Dissolved-solids concentrations range from 44 to 218 mg/L. Data from two aquifer tests indicate transmissivities of 2,500 and 6,000 sq ft/day and storage coefficients of 0.0003 and 0.0007, respectively. The Cockfield aquifer presently provides small to moderate quantities of water for several public and industrial water supplies and small quantities to numerous domestic and farm wells. Withdrawals for public and industrial supplies in 1983 averaged about 3.3 million gal/day. (USGS)

ESTIMATES OF GROUND-WATER FLOW COMPONENTS FOR LYMAN LAKE, APACHE COUNTY, ARIZONA, WITH A SECTION ON GEOCHEMISTRY OF SURFACE WATER AND GROUND WATER IN THE LYMAN LAKE AREA BY FREDRICK N. ROBERTSON.
Geological Survey, Tucson, AZ. Water Resources Div.
D. J. Bills, and H. W. Hjalmarson.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 89-4151, 1990. 55p, 12 fig, 4 tab, 21 ref. Project no. AZ092.

Descriptors: *Arizona, *Lakes, *Lyman Lake, *Surface-groundwater relations, Groundwater, Hydrologic budget, Isotopic tracers, Water quality.

Lyman Lake is an irrigation reservoir on the Little Colorado River near St. Johns, Arizona. The main sources of water for the lake are streamflow in the Little Colorado River and spring flow from the underlying Coconino aquifer. The use of groundwater at two electric-power generating stations in the Lyman Lake area may affect the quantity of spring flow at the lake. The water-budget method and water-chemistry and isotope data were used to compute the quantity of groundwater flow to and from Lyman Lake. Components of flow used in the water budget analysis included evaporation from the lake, transpiration from dense vegetation, seepage through the dam, streamflow in and out of the lake, precipitation on the lake, and measured or estimated changes in lake storage for 7-day periods in 1985 and 1986. Geochemical data included major ions, trace elements, and the stable isotopes of hydrogen and oxygen. During the study, the potentiometric level in the Coconino aquifer was above the lake level at the upstream end of the lake and below lake level at the downstream end. Groundwater flow from the lake is related to the head difference between the aquifer and the lake at the downstream end of the lake. Discharge from the aquifer was an average of 5.7 cu ft/sec at Salado Springs downstream from Lyman Lake and an estimated 6.0 cu ft/sec in Lyman Lake. The relation between computed groundwater inflow and the difference in head between the aquifer and the lake at the upstream end was not statistically significant. The interpretation of the geochemical data supports the conceptual model of the water budget, and the calculated percentages are within the range of the results of the water budget comparison. (USGS)

SELECTED GROUND-WATER INFORMATION FOR THE PASCO BASIN AND ADJACENT AREAS, WASHINGTON, 1986-1989.
Geological Survey, Tacoma, WA. Water Resources Div.
B. W. Drost, K. M. Schurr, and W. E. Lum.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Open-File Report 89-228, 1989. 91p, 2 fig, 2 tab, 8 ref.

Descriptors: *Hydrologic data, *Pasco Basin, *Washington, *Water resources data, *Well data, Data collections.

The U.S. Geological Survey, in cooperation with the United States Department of Energy, conducted a study of the Pasco basin and adjacent areas, Washington, in support of the Basalt Waste Isolation Project at the Hanford site, Washington. The purpose of the study was to develop a data set that would help define the groundwater-flow system of the Pasco Basin. This report contains the basic data, without interpretation, that were collected from the start of the project in February 1986 through January 1989. Information presented is from the U.S. Bureau of Reclamation, State of Washington Department of Ecology, US Army Corps of Engineers, Kennewick Irrigation District, and the Survey, and consists of well location and construction data, records of water levels in the wells, and aquifer designations for each well. The aquifer designation represents the geohydrologic unit to which the well is reported to be open. (USGS)

WATER-QUALITY, WELL CONSTRUCTION, AND GROUNDWATER LEVEL DATA FOR AN INVESTIGATION OF RADIONUCLIDES IN GROUND WATER, HICKMAN AND MAURY COUNTIES, TENNESSEE.
Geological Survey, Nashville, TN. Water Resources Div.
G. E. Hileman.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Open-File Report 90-190, 1990. 13p, 2 fig, 2 tab, 9 ref.

Descriptors: *Groundwater, *Radioisotopes, *Radon, *Tennessee, *Water quality data, *Water resources data, Chattanooga Shale, Geochemistry, Phosphatic limestone, Radionuclides, Trace metals.

Water quality, well construction, and groundwater level data were collected for an investigation of radionuclides in groundwater in Maury and Hickman Counties, Tennessee. Seventeen wells and 3 springs were sampled in Hickman County, and 20 wells were sampled in Maury County. Samples from each site were analyzed for radionuclides, common and trace inorganic ions, indicators of redox conditions, selected nutrients, total organic carbon, and selected physical characteristics. Well-construction data were obtained to help determine the source of the water. Where possible, groundwater level measurements were made for each well sampled. Samples were collected from May 1989 through mid-August 1989. Data are presented in tables. Maps of each county show the location of the sites sampled. (USGS)

Descriptors: *Fort Pillow aquifer, *Groundwater *Groundwater recharge, *Potentiometric level *Tennessee, *Water level fluctuations, Aquifers Fort Pillow Sand, Groundwater movement.

Recharge to the Fort Pillow aquifer of Tertiary age in Tennessee is from precipitation on the outcrop, which forms a narrow belt across western Tennessee, and by downward infiltration of water from the overlying fluvial deposits of Tertiary and Quaternary age and alluvium of Quaternary age or where the upper confining unit is absent, from the overlying Memphis aquifer of Tertiary age. The potentiometric surface in the Fort Pillow aquifer slopes gently westward from the outcrop-recharge area, and the water moves slowly in that direction. A depression in the potentiometric surface in the Memphis area is the result of past pumping by Memphis Light, Gas and Water Division (MLGW) well fields (1924-74), and past and present pumping at an industrial well field at Memphis, and the municipal well field at West Memphis, Ark. Water levels in areas affected by pumping have declined at average rates ranging from 0.4 to 0.9 ft/year during the period 1945-85. The greatest rate of decline was as much as 4.0 ft/year between 1949 and 1954 in an observation well in a well field of MLGW at Memphis. In 1971, MLGW ceased pumping from the Fort Pillow aquifer at this well field, and between 1972 and 1976, water levels rose about 28 ft in this well. Withdrawals from the Fort Pillow aquifer in western Tennessee in 1985 averaged about 12 million gal/day. (USGS)

Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Open-File Report 89-402, 1990. 247p, 5 fig, 1 pl, 7 ta, 35 ref, 4 append.

Descriptors: *Groundwater, *Groundwater pollution, *Hydrogeology, *Hydrology, *New Jersey, *Water quality data, *Well data, Coastal plain, Groundwater level, Groundwater movement, Hydrogeologic units, Hydrologic properties, Potomac-Raritan-Magothy Aquifer System, Water level fluctuations, Water use.

Groundwater beneath a former chemical reclamation facility in New Jersey is contaminated with metals and organic compounds. The off-site migration of these compounds has not been studied; however, a nearby public-supply well is contaminated, and a public-supply well 1,400 ft downgradient from the site may be threatened. The study area, in the New Jersey part of the Atlantic Coastal Plain, is underlain by alluvial deposits composed of gravel, sand, silt, and clay. These deposits comprise the water table aquifer, the confining unit, and the confined aquifer throughout the study area. The water table beneath the Swope Oil Superfund site is approximately 17 ft below sea level, and groundwater levels throughout the study area are below the stage of the Delaware River. The aquifer system is recharged by precipitation, drainage of water through confining units, and by water induced from the Delaware River. Two public supply-well fields, primarily adjacent to the Delaware River, and four waste disposal sites with observation well networks are located in the study area. Both the water table and confined aquifer are contaminated in several locations. The concentration of metals and/or purgeable organic compounds in more than 20 wells exceeds the Environmental Protection Agency primary drinking-water standard and the New Jersey Department of Environmental Protection recommended drinking water criteria. Selected data from soil and test borings are presented, including well

struction details; drillers', geologists', and geophysical logs; water levels; specific-capacity and slug test data; and chemical analysis of groundwater samples. (USGS)

NORTHEAST GLACIAL AQUIFERS.
Regional Aquifer Systems of the United States. Papers presented at AWRA Symposium on Monitoring, Modeling, and Mediating Water Quality, May 17-20, 1987, Syracuse, New York. AWRA Monograph Series No. 11, 1988. 156 p. Edited by Allan D. Randall and A. Ivan Johnson.

Descriptors: *Geohydrology, *Glacial aquifers, *Groundwater resources, *Regional Aquifer-Systems Analysis, *Surface-groundwater relations, Symposium, Aquifers, Glacial drift, Glacial hydrology, Lithology, Radioactive tracers, Runoff.

Papers are presented from the AWRA Symposium on Monitoring, Modeling, and Mediating Water Quality, held May 17-20, 1987. The following topics are discussed: Northeast Glacial Aquifers RASA Project; Upland runoff as a major source of recharge to stratified drift in the glaciated northeast; Estimation of water available for recharge to sand and gravel aquifers in the glaciated northeastern United States; Evaluation of the continuous seismic-reflection methods for determining the thickness and lithology of stratified drift in the glaciated northeast; Continuous seismic-reflection profiling of glacial drift along the Susquehanna, Tioga, and Chenango Rivers, south-central New York and North-Central Pennsylvania; Geochemistry of the stratified-drift aquifer in the Killbuck Creek Valley west of Wooster, Ohio; and, Use of Oxygen-18 and deuterium mass-balance analysis to evaluate induced recharge to stratified drift aquifers. (See W91-02281 thru W91-02287) (Lantz-PTT)

NORTHEAST GLACIAL AQUIFERS RASA PROJECT--AN OVERVIEW OF RESULTS THROUGH 1987.
Geological Survey, Albany, NY. Water Resources Div.
A. D. Randall, and A. I. Johnson.
IN: The Northeast Glacial Aquifers. Regional Aquifer Systems of the United States. Papers presented at AWRA Symposium on Monitoring, Modeling, and Mediating Water Quality, May 17-20, 1987, Syracuse, New York. AWRA Monograph Series No. 11, 1988. p 1-15, 7 fig, 1 tab, 35 ref.

Descriptors: *Geohydrology, *Glacial aquifers, *Groundwater resources, *Regional Aquifer-Systems Analysis, *Surface-groundwater relations, Aquifers, Geochemistry, Groundwater movement, Groundwater recharge, New England, New York, Snowmelt.

The Northeast Glacial Aquifers project, one of the US Geological Survey's many Regional Aquifer-Systems Analyses (RASA), must evaluate a multitude of local aquifers that interact with regional streams but not with each other. These local aquifers were deposited by glacial meltwater and occur chiefly in valleys. The water they contain is generally less highly evolved geochemically than that in bedrock, probably because their small extent and high permeability allows the water to move through them quickly. Studies of the distribution of aquifers within the glacial drift have led to conceptual models of typical aquifer geometries in each of several subregions in the glaciated Northeastern United States. Although such models can help guide evaluation of local aquifers, local data are still needed; one promising new technique for obtaining data is marine seismic reflection, which can delineate aquifer geometry beneath the large streams and lakes that are potential sources of induced recharge. The exchange of water between stratified-drift aquifers and streams is a vital feature of the hydrology of the glaciated Northeast. Runoff from uplands is a major source of recharge to stratified drift under natural conditions, and recharge induced from streams by pumping can far exceed all natural recharge. Rates of induced recharge and streambed properties may be calculated from streamflow measurements, or from vertical temperature profiles beneath the stream, diurnal fluctuation in dissolved oxygen in the streambed, isotopic and dissolved chemical differences between river water and groundwater, or calibration of groundwater flow models. During periods of low flow, natural streamflow consists of groundwater that is discharged into stream channels; its magnitude is a function of the area of surficial sand and gravel in the basin, wetland area, and precipitation. A new modeling technique routes rejected recharge and groundwater discharge from upland hillsides to locations where it can infiltrate sand and gravel on the valley floor. UPLAND RUNOFF AS A MAJOR SOURCE OF RECHARGE TO STRATIFIED DRIFT IN THE GLACIATED NORTHEAST.
Geological Survey, Bow, NH. Water Resources Div.
D. J. Morrissey, A. D. Randall, and J. H. Williams.
IN: The Northeast Glacial Aquifers. Regional Aquifer Systems of the United States. Papers presented at AWRA Symposium on Monitoring, Modeling, and Mediating Water Quality, May 17-20, 1987, Syracuse, New York. AWRA Monograph Series No. 11, 1988. p 17-36. 8 fig, 5 tab, 27 ref.

Descriptors: *Geohydrology, *Glacial aquifers, *Glacial drift, *Groundwater recharge, *Groundwater resources, *Regional Aquifer-Systems Analysis, *Stratified drift, *Surface-groundwater relations, Aquifers, Case studies, Infiltration, New Hampshire, New York, Pennsylvania, Permeability, Runoff.

Most large valleys in the glaciated northeastern United States contain stratified drift that consists partly of sand and gravel. Precipitation on the valley floor has been considered to be the chief source of natural recharge to sand and gravel aquifers, augmented by some groundwater flow through the poorly permeable bedrock and till that form the adjacent uplands. Recent studies of several localities suggest, however, that well over half the natural recharge to stratified-drift aquifers can be derived from upland runoff, by infiltration of streamflow and unchanneled runoff from uplands as well as by lateral flow of groundwater. For example, at least 60% of recharge to a valley in central New York, computed by two independent methods, was ascribed to upland sources. About 58% of recharge to a nearby locality was from upland sources, according to a test application of a detailed method for estimating aquifer yields in south-central New York. More than 85% of recharge to a valley aquifer in north-central Pennsylvania was from upland sources, chiefly infiltration from upland tributaries, which averaged 10.5 cu ft/sec and which prevented persistent declines in water level in a well field new one of the tributaries except when the tributary channel was dry. Nearly 75% of the groundwater that discharged from stratified drift to a 4-mile reach of the Saco River valley in New Hampshire during two periods of low flow was concurrently replaced by seepage of tributary streamflow, and upland sources contributed 59% of the natural recharge as simulated by a steady-state groundwater flow model of the valley. Review of these case histories indicates that, in regions of high topographic relief, upland sources account for about 60% of the recharge to stratified drift in valleys 1 mile wide, and more in narrower valleys. In regions of low relief, seepage losses from tributaries may be small under natural (nonpumping) conditions. (See also W91-02280) (Author's abstract)

F. P. Lyford, and A. J. Cohen.
IN: The Northeast Glacial Aquifers. Regional Aquifer Systems of the United States. Papers presented at AWRA Symposium on Monitoring, Modeling, and Mediating Water Quality, May 17-20, 1987, Syracuse, New York. AWRA Monograph Series No. 11, 1988. p 37-61, 7 fig, 3 tab, 28 ref.

Descriptors: *Geohydrology, *Glacial aquifers, *Groundwater budget, *Groundwater recharge, *Groundwater resources, *Regional Aquifer-Systems Analysis, *Surface-groundwater relations, Aquifers, Hydrologic budget, Infiltration, Runoff, Snow, Snowmelt.

Estimates of the volume of water available annually or monthly for recharge to sand and gravel aquifers in the glaciated Northeast are needed for aquifer modeling and assessment of potential aquifer yield. Sources of recharge include direct infiltration of precipitation on the aquifers, runoff from till-covered upland hillsides bordering the aquifers, and seepage from streams. The volume of water available annually for recharge is generally equal to annual runoff (precipitation minus evapotranspiration). This quantity ranges from 12 to 30 inches over most of the glaciated Northeast. Quantities of water available for recharge from direct infiltration can be estimated by applying the water balance equation to data presented in this paper, to routinely published data on precipitation, snowpack, and temperature, and to evapotranspiration data computed from pan evaporation or various formulas. Quantities available are greatest during November, December, March, and April and generally equal or approach zero from June through September. Quantities may exceed 6 inches per month at higher elevations and latitudes during periods of snowmelt. Quantities of water available monthly for recharge from upland hillslopes and from tributary streams where they cross valley-fill aquifers can be estimated from rates of runoff in upland areas. The Northeast can be divided into six regions, each with a distinctive monthly runoff pattern that is controlled largely by winter snow

accumulation and spring snowmelt. (See also W91-02280) (Author's abstract)

GEOCHEMISTRY OF THE STRATIFIED-DRIFT AQUIFER IN KILLBUCK CREEK VALLEY WEST OF WOOSTER, OHIO.
Geological Survey, Columbus, OH. Water Resources Div.
K. J. Breen.
IN: The Northeast Glacial Aquifers. Regional Aquifer Systems of the United States. Papers presented at AWRA Symposium on Monitoring, Modeling, and Mediating Water Quality, May 17-20, 1987, Syracuse, New York. AWRA Monograph Series No. 11, 1988. p 105-131, 12 fig, 2 tab, 22 ref.

Descriptors: *Geochemistry, *Geohydrology, *Glacial aquifers, *Groundwater quality, *Groundwater resources, *Killbuck Creek Valley, *Regional Aquifer-Systems Analysis, *Stratified drift, *Water chemistry, Aquifers, Chlorides, Glacial drift, Groundwater chemistry, Iron, Manganese.

Water for Wooster, Ohio, is obtained from two well fields developed in the stratified glacial drift of the Killbuck Creek valley. A contamination incident in 1983 closed the city's southern well field and caused increased pumping stress on the aquifer near the remaining well field. As a result, water levels in production wells dropped to record low levels in 1984-85. A geochemical study of groundwater was conducted during this period to evaluate the processes affecting water chemistry. Results indicate that the composition of water produced from the well field is controlled, in part, by the mineralogy of the water-yielding zones and by mixing of water in the drift aquifer with water from the underlying sandstone and shale bedrock. A mixing and mass balance analysis based on sodium and chloride indicates that water from the production well at the center of the well field is about 80% drift water and 20% bedrock water. The percentage of drift water ranges from $< 10\%$ at the easternmost production well to $> 90\%$ at the westernmost production well. The aquifer matrix is comprised mostly of quartz with calcite, dolomite, illite, and iron-chlorite. Groundwater chemistry and the presence of sericitized feldspar, kaolinite, and minerals containing oxidized iron indicate that groundwaters are involved in carbon-oxygen reactions, dissolution and precipitation of carbonate minerals, hydrolysis of silicates, and iron and manganese reactions. These mixing and chemical processes produce an iron-rich, sodium calcium chloride bicarbonate-type water at the central and easternmost production wells. The two westernmost production well waters and the deep drift waters, in general, are an iron-rich, calcium bicarbonate type. (See also W91-02280) (Author's abstract)

USE OF OXYGEN-18 AND DEUTERIUM MASS-BALANCE ANALYSIS TO EVALUATE INDUCED RECHARGE TO STRATIFIED-DRIFT AQUIFERS.
Geological Survey, Albany, NY. Water Resources Div.
J. E. Dysart.
IN: The Northeast Glacial Aquifers. Regional Aquifer Systems of the United States. Papers presented at AWRA Symposium on Monitoring, Modeling, and Mediating Water Quality, May 17-20, 1987, Syracuse, New York. AWRA Monograph Series No. 11, 1988. p 133-154, 13 fig, 2 tab, 15 ref.

Descriptors: *Aquifers, *Deuterium, *Geohydrology, *Glacial aquifers, *Glacial drift, *Groundwater recharge, *Groundwater resources, *Mass balance, *Oxygen isotopes, *Regional Aquifer-Systems Analysis, *Stratified drift, *Surface-groundwater relations, Geochemistry, Hydraulic conductivity, Hydrogen isotopes, Infiltration, New Jersey, Ohio, Recharge.

The environmental isotopes oxygen-18 and deuterium have been used to distinguish between the native groundwater in stratified drift aquifers and stream water that may infiltrate and recharge those aquifers, commonly as a result of large groundwater withdrawals that lower the water table near streams. In the glaciated northeastern United States, the seasonal variation in the values of these isotopes in aquifers is much smaller than in river water. Where groundwater beneath or near a stream consistently has the same isotope values as the stream, infiltration is indicated. Water samples from deep and shallow wells in stratified drift, from bedrock wells, and from streams were collected near municipal well fields in Ohio and New Jersey and analyzed for deuterium, oxygen-18, tritium, and dissolved constituents. The isotope values of water from the pumped wells were compared with those of streams and native groundwater to: (1) estimate the percentage of pumped water that was derived by infiltration from the river; (2) calculate, in conjunction with head measurements, the hydraulic conductivity of the streambed; and (3) evaluate seepage from bedrock into the stratified drift. Infiltration rates calculated from deuterium and oxygen-18 data were in general agreement with those calculated from stream loss measurements. Induced stream infiltration at the New Jersey site was computed to be about 1.4 cu ft/sec with a range of 2.5 to 0.7 cu ft/sec, and streambed hydraulic conductivity was calculated to be about 1.6 ft/day. Induced infiltration at the Ohio site was determined to be negligible, but tributary streams and upward leakage of bedrock water contribute water to the stratified drift aquifer. Current international developments relating to nat
ural and 'man-induced' groundwater recharge ind
cate a number of problems, including the lack of
comprehensive estimation technique, lack o
knowledge about the areal extent of any derive
recharge results, and limited applicability of dat
from any given site and extreme variability in dat
quantity and quality. With these ideas as a frame
work, specific topics are discussed, including: def
nitions (aridity, groundwater recharge), ground
water recharge processes, temporal and spatial va
iability of recharge, resource management implic
tions, and recharge requirements for groundwat
modeling. The final choice of techniques for es
mating groundwater recharge will depend o
study objectives, initial data base and the possibi
ty of supplementing the data base, and availab
financial resources. Although recharge mech
nisms are reasonably well known, deficiencies a
evident in quantifying the various elements. Und
arid conditions recharge is intermittent and co
centrated in small areas; these characteristics ma
point methods preferable to areal methods for es
mation of recharge. Issues relating to spatial a
temporal variability and result regionalizati
create a series of problems for which further inv
tigation is needed. When data are inadequate, as
often the case in developing countries, a flexi
approach to project design can be employed
collect data as resource development procee
Conceptual hydrological models are important
this process. (See also W91-02288) (Rochest

Chloride and tritium methods were employed in a study of recharge in northwest Burkina Faso. Two recharge mechanisms are active in the thick, weathered mantle covered crystalline basement complex in Burkina Faso: (1) diffuse recharge and (2) localized recharge via preferential pathways. Due to the low chloride content in precipitation a chloride balance cannot be used to determine recharge. However, the absence of significant chloride accumulation in the upper soil indicates that the diffuse mechanism is taking place. The distribution of tritium concentrations in the unsaturated zone and in the groundwater indicates that a 'rapid' recharge component also is present. The relative importance of both recharge mechanisms can be obtained only through a combined approach of unsaturated zone and groundwater studies. Large-scale sampling of precipitation chemistry is necessary to obtain representative results. (See also W91-02288) (Rochester-PTT)

In the Gondo Plain (Mali) the groundwater level is declining regularly because of the poor rainfall distribution of the past few years. More and more wells have to be put down in the limestones of the Irma formation, which is overlain by 40-50 m of silt-clay deposits of the 'Continental Terminal.' For the location of productive fissures, several geophysical methods were tested in terms of accuracy. Many productive and dry wells were investigated using original prototype instruments. Low frequency (4 and 4 Hz) geoelectric, very low frequency (12-24 kHz) resistivity (VLF-R), and electromagnetic bipole instruments were compared. Geoelectrical methods were not the best suited to locate small heterogeneities at greater depth hidden by thick conductive overburden. The depth penetration with the VLF-R also was very limited. The electromagnetic bipole seems to be the best tool to get the sharpest contrast on the karstified joints. Horizontal-loop profiling (Slingram method) with optical coil separation of 80 m at 2048 hz was well adapted to realize anomaly maps. These maps make clear that all productive wells are located in those zones where the quadrature values (percent out-phase) are negative. Dry wells are always located in the positive zones of the maps. Multidirectional electromagnetic vertical soundings indicate the degree of anisotropic contrast depending on depth and permit the strike and intensity of the regional joint development to be found. One of the most important advantages of the inductive electromagnetic exploration in arid zones is the speed of data acquisition, because the coils work without soil contact. Descriptors: *Aquifer testing, *Aquifers, *Geophysical studies, *Groundwater mining, *Rural areas, *Wells, *West Africa, Conductivity, Geologic fractures, Gneiss, Granites, Pumps, Resistivity.

In the last few years, some hydrological projects in crystalline formations of West African countries have consisted of supplying villages with drilled wells and pumps. In these areas, economic aquifers usually occur in fissured and fractured zones. To detect such zones in the field, resistivity profiling has been used for a long time: the zones are identified as conductive compartments on resistivity profiles. However, the reverse is not always true. The studies suggest that the best qualitative interpretations can be obtained by using both Schlumberger and square arrays for horizontal profiling. Fracture zones are then identified as a combination of low apparent resistivity and low apparent anisotropy. This methodology, which is well adapted to crystalline formations (granite-gneiss) with thin weathered layers, could indicate accurately the locations of productive wells when applied to a village hydrology project in Benin. Both theoretical and empirical studies support the view that this method is well-adapted to studies of aquifers with fractures and fissures in granite-gneiss. (See also W91-02288) (Author's abstract)

In the Air Massif, in Niger's Sahelian region, the local population farms principally in the valleys. Increased use of water for agriculture and insufficient recharge due to poor rainfall over the past 15 yr, are leading to a serious imbalance. Water requirements for agricultural self-sufficiency are no longer assured and even domestic use is becoming a problem. Situated on the piedmont of the Air Massif, the alluvial aquifer of the wadi, which supplies Agadez (population 45,000) and its agricultural zone, the Teloua, has undergone a drop of 10 m over the last 5 yr. The volume of water penetrating the aquifer during the annual floods no longer compensates for natural loss and use of water in the zone. Most wells are dry despite efforts to deepen them. The alluvial deposits comprising the reservoir are essentially composed of more or less muddy sands and weathered rocks. These deposits block the sedimentary channels at the Air's edges as well as its ancient granitic valleys. In an effort to define the geological and hydrogeological structures of the aquifer and its recharge area and the path and speed of flow, piezometric, geophysical, and multitracing studies were carried out. Paleochannels comprise most of the aquifer and its zone of recharge. (See also W91-02288) (Author's abstract)

The emanation of radon gas through the ground in areas with an igneous or metamorphic basement increases with fracturing of the underlying rock and with its water content. Radon prospecting has been used to complement photointerpretation and electrical geophysics in the search for wells with a yield greater than 5 cu m/hr at three sites in Burkina Faso with differing hydrogeological and climatic conditions. At Sanon there are about ten high-contrast to very high-contrast anomalies (up to 4480 picocuries (pCi)/l) on high background noise (540 pCi/l) despite a 20-50 m clay cover on a basement of migmatites and granites. The wells with the highest yield correspond to the strongest and most extensive radon anomalies and, with one exception, the intersect highly fractured zone. At Katchari the background noise is weak (125 pCi/l) although the sandy clay saprolites of the ampibolitic basement are only of average thickness (14-22 m). The anomalies, not of high contrast, are aligned along the conductive zones revealed by electrical geophysics. The highest yields corresponded to the strongest emanations. Barogo has a varied substratum (schist, diorite, tuff, etc.) situated under 10-40 m of clayey saprolite. The variations in the fairly low level of background noise (average 190 mCi/l) in places mark the lithological changes in the basement. Only one high-contrast anomaly (890 pCi/l) was discovered in a zone with a fairly high background noise (280 pCi/l) despite 32 m of saprolite. The well sunk there yields 25 cu m/hr, the highest yield on this site. Although radon prospecting used as a supplement to conventional methods has yielded very positive results, many questions remain to be answered. (See also W91-02288) (Author's abstract)

Geophysical prospecting for groundwater exploration for rural water supply projects in areas of the Sahel, where the aquifer is discontinuous, can no be considered indispensable for obtaining results capable of justifying the cost. This prospecting, which must be preceded by detailed photogeological studies, is based essentially on geoelectric methods, in particular electrical vertical soundings and resistivity profiles, sometimes associated with magnetic profiles. Geophysical prospecting was conducted in the Republic of Mali to establish the best location for 466 productive wells in 279 villages as part of a project funded by the Italian Technical Cooperation Agency. The large quantity of geophysical and hydrogeological data available made it possible to define both the optimal methods of prospecting and the best interpretation of the findings for the different geologic formations, which are representative of the major discontinuous aquifers in the Sahel. It is concluded that, if the methods are employed carefully and use extreme precision both in the measurements and locating the resistivity anomalies on the ground, geophysical prospecting can give excellent results. In fact, the cost of geophysical prospecting as a percentage of the total cost of a drilled well (3-4% on average) is amply covered by the greater success (up to more than 20%) that can be obtained compared to research based entirely on photointerpretation. Measurements using electrical prospecting or physical methods are influenced by the stratification of the terrain, faults, and diaclases. Consequently, arrangements for the orientation of measurements are important. Numerous experiments and studies have been carried out in the field of electrical prospecting using a multidirectional investigation method. The aim of this technique is to bring into agreement the electrical anisotropy of the rock and the fracturing as determined by aerial photos, satellite imagery, or hydrogeological studies. By combining classical methods (electrical, geophysical) with multidirectional investigations (squares, double rectangle), a methodology has been developed to help hydrogeologists set boreholes in difficult structures. Tests conducted at 10 sites in Liptako (Niger) demonstrated the capability of the method to produce good results in the hands of a competent operator. Results from three of the sites are described in detail as examples. (See also W91-02288) (Rochester-PTT)

Many studies and surveys have demonstrated how useful geophysics can be in groundwater prospecting. In the case of fractured aquifers, the rural water supply projects of the development programs in Sahelian countries have carried out several routine surveys in the bedrock zones to locate water-bearing fractures. Generally only one method was used. Improvements in results can be obtained by appropriate combining of geophysical methods. The study area was northeast of Zinder (Niger) in Precambrian granites. During the 1987-1988 drilling campaign, geophysical prospecting was conducted by combining very low frequency (VLF) mapping with classical electrical profiling and sounding. VLF filtered data (tilt angle and quadrature measurements) were used to obtain, on the field, two different maps of the faulted area allowing for the deduction of direction and relative depth of fractionation. On favorable anomalies, a restricted geophysical survey could then locate the drilling site with greater accuracy. This approach improved the percentage of positive drillings, as well as the average well yield. In addition, placing the pumps on the deepest structures insures that installations will last longer as piezometric level declines continuously. (See also W91-02288) (Rochester-PTT)

Descriptors: *Aquifers, *Geohydrology, *Groundwater resources, *Kenya, *Semiarid lands, Arid lands, Lithology, Regional analysis, Sedimentary basins.

Finding and developing sources of groundwater is becoming an increasingly urgent need in many parts of Kenya. This is particularly critical in arid and semi-arid lands, which form nearly two thirds of the total area of the country. Groundwater sources were investigated in the sedimentary basins of eastern Kenya with the aim of determining aquifer characteristics. Although data are fragmentary and patchy, it is possible to identify three types of aquifers in the area in terms of both depth and lithology. There are shallow aquifers (3-10 m deep), deep aquifers (35-40 m), and deep and fractured aquifers. According to lithology, the first type of aquifer is composed of unconsolidated or poorly consolidated sand and gravel commonly interbedded with clay. The second type consists of semi-consolidated and consolidated conglomerate, sandstone, or shale formations with joints or fractures. The third type of aquifer is in limestone and gypsum beds and generally contains saline water. Further research is needed to make clear the extent of each type of aquifer and to determine the quantity and quality of water in each. (See also W91-02288) (Author's abstract)

The eastern extremity of the Kalahari D thirstland (Botswana) is semi-arid, with a

annual rainfall of 447 mm, most of which falls erratically between October and April. However, there is little or no surface runoff because the water is rapidly absorbed by the thick sand mantle of this region. Recharge in a semi-arid area on the fringe of the Kalahari Desert thirstland in Botswana was calculated using various methods. Recharge to a sandstone aquifer concealed by Kalahari sand was found to be small and limited to the eastern escarpment of the Kalahari plateau. Geochemical and isotopic data supported active recharge, which was quantified by hydrometeorological calculations, numerical aquifer flow modeling, and chloride balance calculations. Initial soil moisture studies were used to study the recharge process. Based on these results, it is suggested that rainfall concentration might permit the retention capacity of the sand to be overcome, thus permitting some limited recharge. Longer-term and more detailed work is needed to confirm this view. (See also W91-02288, W91-02333, and W91-02334) (Rochester-PTT)

e Ntane (formerly Cave) sandstone aquifer stern Botswana) is in the Kalahari Desert, a ni-arid region where mean annual rainfall is a le more than one third of potential evapotranration. Hydraulic testing in this poorly transmise sandstone was performed by long-term pump- tests. Delayed yield influenced the drawdown nore than 40 days of pumping in an unconfined dition. The groundwater resource in the area s calculated as a function of well spacing and ifer transmissivity for siting both in fracture es identified and in the naturally fissured sandne. The results of the resource calculation show a required resource of 35,000 cu m/day is ilable for 25 yr from the 1700 sq km of confined ne aquifer. On a regular grid basis, 175 wells ering 350 sq km would be required. The renewe resource of the whole study area, provided gularly by intermittent recharge, is estimated to ,000 cu m/day. After abstraction for 25 yr, the ndwater level theoretically will have been ered about 40 m when no recharge is consid-. (See also W91-02288, W91-02332, and W91-33) (Rochester-PTT)

The physicochemical composition of groundwater plays an important role not only because of its health impact but in terms of user acceptance, and affects technical aspects (eg, corrosion) as well as industrial and agricultural applications. A general overview of groundwater quality in western Africa is given based mainly on field trials of the World Bank-executed INT/81/026 Handpumps Project, which covered Burkina Faso, Ivory Coast, Ghana, Mali, and Niger, on the 3000 Well Drilling Program in Ghana, and the Helvetas Project in Mali. Physical parameters considered include temperature, pH, electrical conductivity, and turbidity. Chemical constituents investigated were iron, manganese, oxygen, carbon dioxide, ammonium, nitrite, and nitrate. The groundwater occurring in the Handpumps Project area is, in general, of good quality, with a low level of dissolved minerals, which is typical for non-carbonate formations that underlie much of the investigated areas. The predominance of 'acidic' rocks is the major cause of aggressive groundwater. Organic wastes in and around settlements are the single most important source of groundwater pollution in the rural environment. Livestock concentrations around water sources and dirtiness and inadequate drainage of water also cause groundwater pollution. Well pollution is caused by inadequate well construction or defective wells, poorly installed or defective handpumps, and inadequately designed handpumps and handpump corrosion. The problem of corrosive groundwaters in drilled wells has recently become a serious concern throughout the Sahelian areas of West Africa. A preliminary assessment of corrosion was conducted in the Mali Rural Water Supply Project. An investigation method was devised that permits the prior evaluation of the corrosive potential of groundwater in a relatively quick and cheap way, in line with the needs and possibilities of most village water supply projects. The proposed methodology takes into account the parameters that best identify the corrosive nature of groundwaters where iron is a factor, namely, the 'Langelier Index' and 'Tillman's Diagram.' These parameters can be used to conduct an initial evaluation of the water from each well. To assess the groundwaters of a given region, two steps are required: (1) collect and utilize all chemical analysis data concerning groundwaters tapped by existing wells in the project area and (2) perform physical and chemical analyses using rapid spectrophotometric and volumetric methods on the groundwater of each drilled well, with the sample being taken prior to pump installation. The data obtained can be used to calculate the two indexes. Results obtained from a sample of 150 wells in Mali showed that the method was generally adequate for evaluating groundwater corrosivity and for predicting its future development. Descriptors: *Aquifers, *Geohydrology, *Geologic fractures, *Groundwater movement, *Groundwater recharge, *Niger, Groundwater resources, Pumping tests, Saline water, Tectonics, Water chemistry.

Short-duration pumping tests in the Awagadi valley (some 30 km north of Agadez (Niger) demonstrated that the fault was feeding the alluvial aquifer in the valley. This fault had been identified previously through photogeological studies of the catchment. Statistical studies and an analysis of fracturing showed that the direction of the fault corresponds perfectly to the delineation of the tectonics of the region. Investigation of the water chemistry in the northern part of the study area indicates the presence of saline water intrusion (conductivity: 2,000 microS/cm; pH: 8.12; Na(+): 410 mg/L; Cl(-): 360 mg/L; SO4(-): 160 mg/L). This hypermineralization is very probably the effect of another system from which water is also flowing through the faults. (See also W91-02288) (Author's abstract)

INFLUENCE OF CONTINENTAL RIFTING ON THE HYDROGEOLOGY OF THE BAHI DRAINAGE BASIN, DODOMA PROVINCE, CENTRAL TANZANIA.
Cooperative Inst. for Research in Environmental Science, Boulder, CO. Center for the Study of Earth from Space.
J. C. Brock, and R. F. Arenz.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 648-659, 10 ref.

Descriptors: *Geohydrology, *Groundwater movement, *Groundwater resources, *Remote sensing, *Satellite technology, *Tanzania, *Tectonics, Bahi Swamp, Chenene Hills, Rifts, Vegetation.

The control of rift-associated geologic structuring on the surficial and groundwater flow patterns of the Bahi Drainage Basin on the southern extent of the East Africa Rift (Tanzania) was investigated. Landsat multispectral scanner (MSS) image data were used to infer the presence of rift-associated regional faulting. A Landsat MSS scene was digitally processed to enhance the depiction of structurally controlled geomorphology and hydrogeologic features. Image processing procedures applied to all four MSS spectral bands included geometric rectification to a Universal Transverse Mercator map projection and contrast enhancement by linear stretch operations. The interpretations of linear faults and fracture trends was enhanced by the spatial frequency filtering of all four bands followed by the generation of band composite images. Vegetation index images were generated using a linear combination of MSS bands. The resultant images supported the interpretation of possible groundwater recharge areas and active stream channels. The distribution of potential alluvial aquifers and the drainage pattern was inferred from false-color composite images derived from the contrast-enhanced MSS bands and high pass directional spatial frequency filtered images. The Chenene Hills occupy the south-central portion of the study area, Bahi Swamp is situated to the southwest and Dodoma City lies at the southern limit of the study area. A major northeast-southwest trending fault zone extending from the northern Bahi Swamp and passing immediately to the north of the Chenene Hills was mapped based on Landsat MSS image data and previous geologic field investigations. It is proposed that this fault trend has disturbed a pre-existing northwest-southeast trending drainage system and caused the southwestward diversion of both surface and groundwater flow into the Bahi Drainage Basin. This may have results in the formation of the Bahi Swamp in a closed topographic depression west of the Chenene Hills. Accordingly, the regional northeast-southwest striking fault trends to the northeast of the Bahi Swamp are recommended for groundwater exploration. (See also W91-02288) (Author's abstract)

Descriptors: *Groundwater movement, *Groundwater recharge, *Isotopic tracers, *Mali, *Piezometric head, *Tracers, Carbon isotopes, Evaporation, Groundwater resources, Interior Delta, Mathematical models, Nara Region, Simulation, Tritium, Water table.

An environmental study on the piezometric depressions of the 'Nara' region (northwest Mali) and 'Interior Delta' (central part) led to two conclusions. First, the absence of a logical distribution of radioactive water content (tritium and 14C) from the margin toward the center of the depressions demonstrates predominance of vertical movement over lateral water transfers; the seasonal recharge of the phreatic aquifer does not appear to be followed by regional circulation. Second, the clear relationship between isotopic enrichment and water table depth corresponds to the flushing of heavy isotopes accumulated in the unsaturated zone during the dry season. The evaporation flux, estimated at about 500 mm/yr at 1 m depth, decreases exponentially with depth (1 mm/yr at 15 m). These values, when employed in a mathematical simulation model gave a satisfactory fit between observed and calculated isopiezes. Considering that no recharge occurs in the central part of the basin, this evaporation flux would be sufficient to create and maintain piezometric depressions. TURBULENT FLOW THEORY FOR AFRICAN REGOLITHS.
Utah International, Inc., San Francisco, CA.
N. Krishnamurthi.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 672-685, 3 fig, 3 tab, 1 ref, append.

Descriptors: *Africa, *Groundwater movement, *Mathematical models, *Model studies, *Regoliths, *Sahel, *Turbulent flow, *Well yield, Aquifers, Geologic fractures, Groundwater recharge, Laminar flow.

Current groundwater flow theories are applicable to aquifers of granular materials. The conventional concepts of transmissivity, storage coefficient, and cone of depression may fail to explain turbulence that can be witnessed in a dug well in hard rocks. A fresh approach is needed to model the flow and the well yield in hard rocks like the African regoliths. A turbulent flow model was developed for simulating the flow in African regolithic aquifers. Three assumptions were made in developing the model: (1) flow into a well is through small conduits through the inner surface of the well; (2) water travels from a distance R (assumed constant) from the well; and (3) the operative depth of the well is reckoned below the static water level and there is no flow into the well above this static water level. Equations describing this model are developed in detail and well function and flow conductance, pumping test and analysis, and laminar inflow theory for hard rock open wells are discussed in detail. The model in its current form is suited for field testing in the Sahelian region because of the recharge potential there. (See also W91-02288) (Rochester-PTT)

IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 701-710, 6 fig, 6 ref.

Descriptors: *Aquifer characteristics, *Burkina Faso, *Calcite, *Geochemistry, *Geohydrology, *Hydrologic models, *Water chemistry, Clays, Microscopy, Quartz, Schist.

Borings conducted in Birrimien volcano-sedimentary schists (Burkina Faso) show solution features within quartz veins. Microscopic study of thin sections revealed the presence of calcite, intermingled with the quartz and generally recrystallized, forming an integral part of the lithological unit. Comparison of hydrochemical data from granitic and schist aquifers shows that calcite solution is mainly active in schistose rocks and occurring on a regional scale. Clayey weathering products and a more plastic deformation, a result of stress, make the currently adopted geologic model for granitic aquifers ('valley fill' model) non-applicable to schistose rocks. The calcite solution process is of major importance in developing an acceptable hydrogeological model for schist aquifers. (See also W91-02288) (Author's abstract)

There is great controversy among meteorologists and ecologists about the causes of the persistent Sahelian drought. In all development planning for the Sahel, high levels of climatic variability and inevitable drought are accepted as 'normal.' Sahelian countries can benefit by knowledge of deep aquifers in the Libyan Sahara. The Kufra Production Project (KPP), Kufra Settlement Project (KSP), and the Sarir Production Project (SPP) have been operating for over 15 yr. Systematic monitoring data coupled with two-dimensional and three-dimensional modeling provide unique hydrological insight into the extraction of water for large-scale projects, such as the Great Man Made River Project. Based on experience from the Libyan projects, a plan is presented for development of groundwater resources for agriculture in the Sahelian countries. The magnitude of sustainable development does not depend on knowing the total water budget but does depend on the degree of hydrological effects that can be tolerated at any given time. A plan for study would include the following eight steps: (1) use satellite-derived data for basic geological and hydrogeological information; (2) conduct general geologic reconnaissance; (3) conduct hydrologic reconnaissance; (4) pursue test exploration and production wells for 5-day and 10-day periods to determine preliminary aquifer parameters and water quality; (5) construct a numerical identification model using all the collected data; (6) use the model and other tools (e.g., geologic maps, aerial photos, geophysical logs) to locate well fields in areas with soils suitable for growing crops; (7) employ a modern well design for high performance production; and (8) use data from the well fields to update the original three-dimensional model every year. Descriptors: *Burkina Faso, *Groundwater recharge, *Groundwater resources, *Rural areas, *Water supply development, *Wells, Aerial photography, Geohydrology, Groundwater movement, Infiltration, Isotopic tracers, Pumping tests, Water supply, Well yield.

Ongoing village water supply drilling programs and detailed hydrogeological field studies (comprising core drillings, long-duration pumping tests, hydrochemical and isotope analyses, etc.) have been combined to study the basic characteristics and the recharge of aquifer systems of the crystalline shield in Yatenga Province, northwest Burkina Faso. The characteristics of the aquifers appear to be determined primarily by the lithology of the underlying bedrock. On granitic rock, the fractured zone is in continuous hydraulic contact with the overlying weathered zone and they react during pumping tests as one hydrologic medium. On schistose rock, a remarkable difference in permeability exists between the clayey alterites and the fractured bedrock. Hydrochemical and isotope analyses show that recharge by diffuse infiltration is limited (40-140 mm/yr) and slow (less than 0.3 m/yr) and a non-negligible part of the recharge takes place as rapid drainage via preferential paths (localized recharge). Interpretation of aerial photos and geophysical investigations show that the best drilling locations for village water supply programs are situated on the coincidence of major structural lineaments and the lower part of the erosional glacis. scriptors: *Alberta, *Groundwater movement, akes, *Limnology, *Narrow Lake, *Nutrients, hosphorus, Darcys equation, Mathematical dels, Piezometry, Seepage.

integrated approach was used to quantify undwater phosphorous flux to Narrow Lake, a small glacial terrain lake in central Alberta. Data from a drilling program, major ion concentrations, environmental isotopes, and computer simulations indicated that the lake gains water through the nearshore region, from a small shallow groundwater flow system; at deep offshore regions, water moves from the lake to the groundwater flow system. Seepage flux was quantified by water budget, Darcy's equation with data from wells near the lake, Darcy's equation with data from minipiezometer in the lake, and seepage meters. Whole lake seepage flux determined from minipiezometer data (30 mm/yr) was only 10-25% of the other estimates (mean, 221 mm/yr; range, 133-332 mm/yr from seepage meter and water budget data, respectively). Groundwater contributed 30% of the annual water load to the lake. The P concentration in pore water from lake sediments (mean, 175 mg cu m) was 8 times higher than groundwater from wells near the lake (mean, 21 mg m cu). Thus, if well water was used to estimate P concentrations of the seepage water, the rate of groundwater P loading to the lake would be underestimated. The rate of groundwater P loading to the lake computed from average seepage flux and average pore water P concentration was 39 mg sq m/yr, and groundwater may be the largest single source of P to epilimnetic water in the lake. Limnology and Oceanography LIOCAH, Vol. 35, No. 4, p 931-938, June 1990. 5 fig, 1 tab, 28 ref. NSF Grant Int 83-19271.

Descriptors: *Groundwater recharge, *Lake Chad, *Limnology, *Salinity, *Salt balance, *Surface-groundwater relations, *Water chemistry, Africa, Aquifers, Flow rates, Groundwater movement, Piezometry, Seepage, Water table.

The open waters of Lake Chad are reasonably free of salt (120-320 mg/L) even though it is a shallow, old, closed-basin lake located in the highly evaporative environment of sub-Saharan Africa. It is possible that the lake remains relatively fresh due to the significant removal of water and solutes by seepage into the groundwater beneath the lake. Directly measured seepage rates (seepage meters and core tracer methods) through the sandy lake bottom are 0.00115 m/d. The regional water table derived in this study indicates the lake to be at a higher hydraulic elevation than the phreatic aquifer hydraulic elevation, and measurements of the groundwater flow direction determined from minipiezometric nests confirm that flow is SW, away from the lake. Preliminary calculations indicate that seepage plays a significant role in water and solute budgets, since it removes as much as 18% of the annual water input and 40-160% of the annual salt input to the lake. For most hydrogeological problems, and particularly in heterogeneous porous media, the global permeability (or transmissivity) of the aquifers is the most important parameter to be determined for long-term predictions. In practice, the most common methods used by hydrogeologists to determine these parameters consist in radial pumping or injection tests. Two approaches can thus be considered: (1) performing numerous short duration tests and then to calculate from these local values a global estimation of the transmissivity; and (2) performing long-term pumping tests where the value of the effective transmissivity is obtained directly by classical methods of interpretation. The results of the two approaches for the estimation of the global transmissivity were compared by means of numerical simulations. The slug test or injection test over a small section of a well or piezometer when performed at numerous locations is suitable to determine both the type of distribution and the variogram of the local permeability values. Long-term pumping tests can be used as a means to validate the averages which could be obtained from local measurements. The mean transmissivity value established from such a test is identical to the one derived by averaging results from local tests. Thus both methods seem to lead to similar results. Long-term pumping tests are indeed very costly, and do not provide sufficient information on the variability of the system unless a large number of piezometers is available. Descriptors: *Aquifer characteristics, *Geohydrology, *Model studies, *Oil fields, Algorithms, California, Hydraulic conductivity, Numerical analysis, Oil shale, Parametric hydrology, Sand aquifers, Stochastic models, Structural geology, Uncertainty.

A prior requirement to the use of a numerical model is the assignment of aquifer parameter values to the blocks of the model. Data available are few, sparse, and typically vary in space in a way that cannot be deterministically reproduced. This variability introduces uncertainty in the predicted parameter values, which will be responsible for uncertainty in the final response of the model. A new algorithm for stochastic conditional simulations has been used to generate images of the Wilmington oil field (Los Angeles, California, basin) sand-shale sequence. The range of the variable under study was subdivided into mutually exclusive classes and an indicator was associated with each class. Indicator covariances were used to characterize the random geometric pattern between classes. These indicator covariances can be used to include structural qualitative information, such as the expected amount of random shales or the expected geometric continuity of any given class or rock type. When there are not enough data to infer precisely all indicator covariances a sensitivity analysis can be performed and a visual selection among images generated using different covariance models can help in the selection of the correct covariance model. Such selection amounts to the use of implicit geological information/interpretation in the covariance modeling. (See also W91-02672) (Author's abstract) (Fish-PTT)

Descriptors: *Aquifer characteristics, *Geostatistics, *Groundwater management, *Groundwater movement, *Kriging, *Model studies, *Statistical methods, *Transmissivity, *Water resources management, Chile, Data interpretation, Linear programming, Regression analysis, Specific capacity.

Deterministic numerical models simulating the behavior of groundwater are useful tools in the evaluation, planning, and management stages of this resource. More sophisticated and elaborate models are continuously being proposed. However, the information available is usually limited and subject to large sampling and interpretative errors. To overcome these difficulties, it then becomes necessary to introduce into these models the effects of quality, quantity, and spatial distribution of the input data. Three geostatistical methods to estimate the transmissivity of an aquifer using the information commonly available were developed: simple kriging, kriging combined with linear regression, and co-kriging. A comparison was performed between the accuracy of the estimations. In a study of the Santiago aquifer, Chile, it was observed that kriging combined with linear regression gave better estimates, by taking into account the additional information contained in the specific capacity values, which greatly improves the estimation of the transmissivity of an aquifer. The groundwater potential in crystalline rock t rains depends on post-emplacement processes su as tectonism and weathering which could lead the development of secondary porosity and perm ability. Geophysical and hydrochemical techniq have been used to assess the groundwater pr pects in the crystalline weathered regolith in sou western Nigeria. The resistivity measureme gave an average depth of weathering of 34 From a consideration of the hydrodynamics of weathering process, kaolinite was found to be stable clay weathering product indicating t weathering reaction products are being flus since otherwise feldspar-water equilibrium wo have been attained considering the Pre-Camb age of the rocks. The presence of kaolinite taken to imply that the groundwater is being charged but it was not possible to use the avail data to quantify the recharge. Analysis of recov observations on one of the large diameter w sampled gave an average permeability of 50 m (1.2 m/day). These results indicate that the we ered regolith in the study area could sup modest water demands. Some rethinking ma necessary regarding generalizations in the li ture vis-a-vis the groundwater potential in rock terrains. (See also W91-02672) (Author's stract)

Descriptors: *Artificial intelligence, *Computer models, *Finite element method, *Graphical analysis, *Hydrologic models, *Mapping, *Model studies, Geohydrology, Graphical methods, Groundwater management, Groundwater movement, Groundwater pollution, Parametric hydrology, Water quality management, Water resources management.

An interactive groundwater modeling system, based on a two-dimensional finite element simulator, has been developed. Combining a finite element model for flow and transport problems with artificial intelligence (AI)-based and symbolic graphics user interface, the system is designed to allow the easy and efficient use of complex groundwater modeling technology in a problem-oriented rather than model-oriented style. Implemented on a color-graphics engineering workstation, the system provides a problem manager that allows the selection of site-specific, as well as generic, groundwater problems from problem libraries, or the interactive design of a new problem. These problems can be edited and modified and then simulated under interactive user control. The system also features an extensive Intelligent Computer Aided Design (ICAD) component that allows the user to design very efficiently, and parametrize, a new problem from the very beginning, using a map or an auxiliary grid as a background for the definition of problem geometry and hydrogeological parameters. INTEGRATED FINITE DIFFERENCE MODEL FOR GROUNDWATER FLOW AND QUALITY SIMULATION.
Bologna Univ. (Italy). Facolta di Ingegneria.
Ferraresi.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 321-330, 5 fig, 9 ref. National Public Education Ministry of Italy grant MPI 8903002.

Descriptors: *Finite difference methods, *Groundwater movement, *Groundwater quality, *Hydrologic models, *Model studies, *Path of pollutants, Aquifer characteristics, Geohydrology, Groundwater management, Mathematical analysis, Porous media, Water quality management, Water resources management.

Although the integrated finite difference method represents a powerful numerical technique for solving problems of groundwater flow in porous media, scant attention has been paid to its application to real world geohydrological studies. An integrated finite difference model for groundwater flow and quality simulation has been developed. It can deal with multidimensional, multilayered, heterogeneous, anisotropic media, both in confined and phreatic conditions. Its mathematical structure combines the advantages of an integral formulation, which allows complex geometry problems to be solved more easily than by classical finite difference methods, with the simplicity of gradient evaluation, which can be regarded as an advantage over finite element techniques. Comparison with analytical and numerical results does not offer argument for rejecting the choice of the integrated finite difference approach, while the operational activities needed for the input preparation and the model calibration seem more expeditious when this methodology is applied. LOCALIZED ADJOINT METHODS: APPLICATION TO ADVECTION DOMINATED FLOWS.
Universidad Nacional Autonoma de Mexico, Mexico City. Inst. de Geofisica.
I. Herrera.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 349-357, 10 ref.

Descriptors: *Advection, *Groundwater, *Hydrologic models, *Mathematical models, *Model studies, *Path of pollutants, Algorithms, Boundary conditions, Probability distribution, Water quality management, Water resources management, Water transport.

The numerical solution of the advective-diffusive transport equation is a problem of great importance because many problems in science and engineering involve such a mathematical model. Solution of advection-dominated transport problems by discrete interior methods is usually accomplished by employing some type of upstream weighting. Upwinded finite element formulations have also been constructed. At present, a new procedure is being developed, based on Herrera's algebraic theory of boundary value problems, which systematically uses localized adjoint formulas. For one-dimensional steady state problems the procedure yielded very efficient and highly accurate algorithms which compare favorably with those previously available. For time-dependent one-dimensional cases the two algorithms applied corresponded to using two different weighting functions. Two test problems were treated to evaluate the performance of the new method: the propagation of a step discontinuity and that of a Gaussian distribution. The results and the efficiency of the procedure were compared with other methods, testing the effect of changing several parameters. The conclusion was reached that the solutions obtained with this method are at least as good as those obtained using the best available interior methods. Similar conclusions were drawn for two-dimensional problems. in general, localized adjoint methods allow very effective treatment of boundary conditions, but this is especially evident for two-dimensional problems, as a result of their greater difficulty. TARGET LEVEL GROUNDWATER MANAGEMENT MODEL WITH LINEARIZED FLOW AND TRANSPORT CONSTRAINTS.
Commonwealth Scientific and Industrial Research Organization, Wembley (Australia). Div. of Water Resources.
S. A. Prathapar.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 369-380, 6 fig, 2 tab, 4 ref.

Descriptors: *Groundwater management, *Groundwater movement, *Groundwater pollution, *Hydrologic models, *Model studies, *Path of pollutants, *Solute transport, *Water quality management, *Water resources management, Australia, Optimization, Potentiometric level, Simulation analysis, Water table fluctuations, Water table gradient.

Simulation and optimization models are usually combined to determine groundwater management strategies, because it is unlikely that optimal groundwater management alternatives which comply with groundwater hydraulics could be determined by either simulation or optimization models alone. A two-dimensional groundwater management model with linearized flow and transport constraints was developed to determine stresses required to lower a water table to target levels. The linearized Boussinesq equation is embedded as the initial solute transport constraint, assuming constant potentiometric gradients. In addition, a mass balance equation for solutes is embedded to account for changes in concentration due to changes in potentiometric heads. Girgarre, Victoria, Australia was selected as the study area. Strategies determined by the management model with and without solute transport constraints were verified by a two-dimensional solute transport simulation model. Assumptions made with regard to solute transport constraints were satisfactory when concentration gradients were gradual. Smaller time steps will be required to determine stresses for management of aquifers where steeper concentration gradients exist. (See also W91-02672) (Fish-PTT)

MODELING OF VARIABLE DENSITY FLOW, APPLICATION TO THE MANAGEMENT OF COASTAL AQUIFERS (MODELISATION DES ECOULEMENTS A DENSITE VARIABLE, APPLICATION A L'EXPLOITATION DES AQUIFERES COTIERS).
Bureau de Recherches Geologiques et Minieres, Orleans (France).
J. P. Sauty.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 393-404, 6 fig, 12 ref. (English summary).

Descriptors: *Coastal aquifers, *Flow models, *Groundwater management, *Groundwater movement, *Hydrologic models, *Model studies, *Saline water intrusion, *Water quality management, *Water resources management, Density stratification, Finite difference methods, Flow equations, Saline-freshwater interfaces, Seawater, Simulation analysis, Three-dimensional model.

The modeling of variable-density flow in aquifers is useful for many applications. The production of fresh water from coastal aquifers partially invaded by seawater is a particular case of high concern for the management of maritime provinces. The use of models is necessary for understanding the phenomena, predicting the impact of new installations and optimizing freshwater production while keeping control of the inland progression of the salt water interface. Usual modeling techniques simplify the problem to a two-dimensional scheme (horizontal plane or vertical cross-section); unfortunately the modeling of real cases often requires a full three-dimensional approach. A simulation technique based on a particle tracking method is proposed;

the density of the particle population determines the local volume mass of the fluid. The vertical density gradients simply yield source terms in the equation for flow, which is solved by finite differences, in terms of water pressure. The resulting code (named TED for Transport with Effect of Density) is checked against two solutions: (1) the position of the salt water wedge close to the coast, and (2) the coning caused by drainage of fresh water above an initially horizontal interface. MICROBIAL COLONIZATION OF AQUIFER SEDIMENT EXPOSED IN A GROUNDWATER WELL IN NORTHERN GERMANY.
Kiel Univ. (Germany, F.R.). Inst. fuer Allgemeine Mikrobiologie.
P. Hirsch, and E. Rades-Rohkohl.
Applied and Environmental Microbiology AEMIDF, Vol. 56, No. 10, p 2963-2966, October 1990. 1 fig, 3 tab, 16 ref.

Descriptors: *Aquifers, *Germany, *Groundwater quality, *Microorganisms, *Sediment analysis, Carbon cycle, Interstitial water, Microbiological studies, Population dynamics, Wells.

Microbial growth within the water-saturated subsurface environment was investigated by exposing sandy sediments to groundwater for 12 weeks, at a depth of 10 or 20 m in a stainless-steel groundwater well. Washing and heating the sediment to 600 C (removal of organic carbon) prior to the exposure did not prevent the natural microbial community from colonizing the sterilized sediment samples. Total cell counts of more than 10 or 100 million/g of dried sediment were obtained. Viable cell counts of 100,000 cells/g on oligotrophic media indicated the presence, within the exposed sediment, of a highly active and multiplying biota. Microscopic analysis of enrichments inoculated with exposed sediment samples revealed a total of 45 different morphotypes, approximately 42% of the microbial community observed in studies of this site. The interstitial water running off of the retrieved sediment contained only 17 morphotypes and had 600,000 viable cells/ml. (Author's abstract)

EXPERIMENTAL INVESTIGATION OF VARIABLE DENSITY FLOW AND MIXING IN HOMOGENEOUS AND HETEROGENEOUS MEDIA.
Ohio State Univ., Columbus. Dept. of Geology and Mineralogy.
R. A. Schincariol, and F. W. Schwartz.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2317-2329, October 1990. 14 fig, 5 tab, 29 ref.

Descriptors: *Density stratification, *Groundwater movement, *Heterogeneity, *Homogeneity, *Mixing, *Saline water intrusion, *Varied flow, Groundwater, Hydraulic conductivity, Porous media.

Variable density groundwater flow in homogeneous, layered and lenticular porous media was studied. At the scale of the experiments the flow of dissolved mass in water depends upon both forced and free convection. In addition, density differences as low as 0.0008 g/cc (1000 mg/L sodium chloride) between a plume of dense water and ambient groundwater in a homogenous medium produces gravitational instabilities at realistic groundwater velocities. These instabilities are manifested by lobe-shaped protuberances that formed first along the bottom edge of the plume and later within the plume. As the density difference increases to 0.0015 g/cc (2000 mg/L sodium chloride), 0.0037 g/cc (5000 mg/L sodium chloride), or higher, this unstable mixing due to convective dispersion significantly alters the spreading process. In a layered medium, reductions in hydraulic conductivity of the order of half an order of magnitude or less can influence the flow of the dense plume. Dense water may accumulate along bedding interfaces, which when dipping can result in plume migration velocities larger than ambient groundwater velocities. In a lenticular medium the combination of convective dispersion and nonuniform flow due to heterogeneities result in relatively large dispersion. Scale considerations, further, indicate that convective dispersion may provide an important component of mixing at the field scale. (Author's abstract)

Descriptors: *Dispersion, *Groundwater, *Groundwater movement, *Unsteady flow, Aquifer characteristics, Aquifers, Dispersivity, Flow characteristics, Scaling, Solute transport, Storativity, Temporal distribution.

Effects of large-scale temporal velocity fluctuations, particularly changes in the direction of flow, on solute spreading in a two-dimensional aquifer are generally believed to result from spatial variability in aquifer properties. Relations for apparent longitudinal and transverse dispersivity are developed through an analytical solution for dispersion in a fluctuating, quasi-steady uniform flow field, in which storativity is zero. For transient flow, spatial moments are evaluated from numerical solutions. Ignored or unknown transients in the direction of flow primarily act to increase the apparent transverse dispersivity because the longitudinal dispersivity is acting in a direction that is not the assumed flow direction. This increase is a function of the angle between the transient flow vector and the assumed steady state flow direction and the ratio of transverse to longitudinal dispersivity. The maximum effect on transverse dispersivity occurs if storativity is assumed to be zero, such that the flow field responds instantly to boundary conditions. Theoretical and field analyses indicate that longitudinal dispersivity is scale-dependent in porous media and that transverse dispersivity is generally one or more orders of magnitude smaller, causing solute plumes to be long and thin. Descriptors: *Fracture permeability, *Geologic fractures, *Groundwater movement, *Model studies, *Solute transport, *Statistical models, Dispersion, Flow equations, Hydrologic models, Injection, Tracers.

Model fractures with variable apertures were generated by a statistical method, and water flow and tracer transport in these fractures are calculated. Tracer injection and collection are simulated for parallel and convergent flow fields. The impact of the use of different injection flow rates and the different locations of injection and collection points indicates that the transport time, dispersion and the so-called mass balance fracture aperture are very sensitive to the location of the injection point and the injection flow rate. These anomalous effects appear to be consistent with observations in several recent field experiments. The implications of the calculated results on the analysis of tracer tests concludes that because of the stochastic nature of variable fracture apertures (and the permeabilities) a point tracer test in a fracture is not sufficient to characterize the properties of the fracture. Dispersivities and apertures calculated from different tracer tests in the same fracture may vary by orders of magnitude depending on the flow rate and the location of the injection. However, a line injection of tracer, averaged over a series of adjacent points, may avoid some of these problems. (Author's abstract)

Water Resources Research WRERAQ, Vol. 26, No. 10, p 2445-2453, October 1990. 8 fig, 2 tab, 31 ref. National Science Foundation Contract No. BSR 8514430.

Descriptors: *Groundwater, *Hydrologic budget, *Isotope studies, *Lakes, *Mass balance, *Surface-groundwater relations, *Wisconsin, Aquifers, Effluent water, Influent water, Mathematical models, Piezometers, Seepage, Spatial distribution, Temporal distribution.

Groundwater inflow and outflow contributions to the hydrologic budget of lakes can be determined using a stable isotope (oxygen-18/oxygen-16) mass balance method. The stable isotope method provides a way of integrating the spatial and temporal complexities of the flow field around a lake, thereby offering an appealing alternative to the traditional time and labor intensive methods using seepage meter and an extensive piezometer network. This method is applied to a lake in northern Wisconsin, demonstrating that it can be successfully applied to lakes in the upper Midwest where thousands of similar lakes exist. Inflow and outflow rates calculated for the Wisconsin lake using the isotope mass balance method are 29 and 54 cm/yr, respectively, which compare well to estimates, derived independently using a three-dimensional groundwater flow and solute transport model, 20 and 50 cm/yr. Such a favorable comparison lends confidence to the use of the stable isotope method to estimate groundwater exchange with lakes. In addition, utilization of stable isotope

tudies of groundwater-lake systems lends insight ito mixing processes occurring in the unsaturated one and in the aquifer surrounding the lake and erifies assumed flow paths based on head meas-rements in piezometers. (See also W91-02874) Author's abstract)

hree-dimensional groundwater flow and solute nsport model was calibrated to a plume of water cribed by measurements of delta-oxygen-18 and l to calculate groundwater inflow and outflow s at a lake in northern Wisconsin. The flow del was calibrated to observed hydraulic gradi-and estimated recharge rates. Calibration of solute transport submodel to the configuration stable isotope (oxygen-18) plume in the contig-aquifer on the downgradient side of the lake vides additional data to constrain the model. A l match between observed and simulated tem-l variations in plume configuration indicates the model closely simulated the dynamics of eal system. The model provides information natural variation of rates of groundwater w, lake water outflow, and recharge to the r table. Inflow and outflow estimates compare ably with estimates derived by the isotope balance method. Model simulations agree field observations that show groundwater w rates are more sensitive to seasonal vari-s in recharge than outflow. (See also W91-) (Author's abstract)

A spectrally based perturbation approach is used to evaluate the concentration variability for a steady concentration field in a three-dimensional statistically homogeneous and anisotropic aquifer. The analysis assumes small, locally stationary concentration perturbations, and consequently, is valid only after mean displacements that are large compared to the scale of aquifer heterogeneity. The concentration variance is proportional to the square of the local mean concentration gradient and the variance and the correlation scales of log-hydraulic conductivity (ln K) and is inversely proportional to the local dispersivity. The concentration covariance function is highly anisotropic, with the largest correlation length aligned to the mean flow direction. Another important finding is the sensitivity of the longitudinal persistence of the concentration field to the high wave number behavior of the input ln K spectrum. The commonly employed exponential-type covariance function, which corresponds to a nondifferentiable random field, results in extremely large concentration correlation lengths along the flow direction. Input spectra corresponding to differentiable fields with more rapid high wave number cutoffs produce a significant reduction of the longitudinal correlation length. (Author's abstract)

The removal of soluble contaminants from fractured porous bedrock by means of a recovery well was modeled by means of a lumped parameter approach. This simple mathematical model, well-adapted for use with readily available microcomputers, yielded results which depended on the various parameters of the model in intuitively expected ways. A laboratory column model in this study was helpful, within limits, in evaluating some parameters needed in the field flushing models. The use of local equilibrium models for the flushing of fractured bedrock can be expected to yield removal times which are only a small fraction of the time which will actually be required, due to the slow release of contaminant by diffusion from the immobile pore liquid. The situation could be generally worse than what was obtained in this study in which medium block radii of the order of a few centimeters were used, while spacing of the fractures could easily be a meter or more. An increase in the block size by a factor of 10 resulted in a decreased in the time constant for diffusion transport by a factor of .01. Diffusion transport may very well be a severely limiting factor in the rate of cleanup of sites by pump-and-treat operations. (See also W85-06290) (Medina-PTT)

2G. Water In Soils

PORE SIZE, PARTICLE SIZE, AGGREGATE SIZE, AND WATER RETENTION.
Minnesota Univ., St. Paul. Dept. of Soil Science.
L. Wu, J. A. Vomocil, and S. W. Childs.
Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 952-956, July/August 1990. 3 fig, 3 tab, 22 ref.

Descriptors: *Particle size, *Pore size, *Soil aggregates, *Soil moisture retention, *Soil water, Mathematical analysis, Soil properties, Soil texture, Soil types, Statistical analysis.

Measurements of water retention and pore-size distribution for a soil are time consuming and affected by changes in aggregate-size distribution. A method of compared distribution curves was used to relate distributions of pore size (PO), particle size (PA), aggregate size (AG), and pore size from water retention (WR). Seven surface soils varying in texture and aggregation were tested. After normalization to 100% volume, the pore-, particle-, and aggregate-size distribution, as well as water-retention (converted to pore diameter) curves were each fitted to a linearly transformed logistic function to evaluate their interrelations using R(m/n), a coefficient for the ratio of the diameters of component m to component n. Identical distribution curves have an R(m/n) value of 1. The R(PO/PA) and R(WR/PA) for the seven soils ranged from 0.25 to 2.26 and from 0.18 to 1.34, respectively, indicating that the theoretical packing parameters of 0.225 to 0.414 do not hold for PA distribution. The R(PO/AG) ranged from 0.06 to 0.23 and R(WR/AG) from 0.04 to 0.16. Both ranges of R values smaller than the theoretical packing parameters suggests interactions may occur between large and small aggregates. However, R(PO/AG) and R(WR/AG) values were more consistent and were significantly related to aggregation level and bulk density, suggesting that AG distribution should be used as a parameter to predict PO distribution and water retention. Comparisons between water retention curves and PO distributions from Hg intrusion gave R(PO/WR) ranging from 0.78 to 2.59, showing that equivalent PO for a given soil is not the same when different measuring methods are used. COUPLED WATER AND HEAT TRANSPORT IN RIDGED SOILS.
Iowa State Univ., Ames. Dept. of Agronomy.
J. G. Benjamin, M. R. Ghaffarzadeh, and R. M. Cruse.
Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 963-969, July/August 1990. 7 fig, 3 tab, 26 ref.

Descriptors: *Heat transfer, *Mathematical models, *Model studies, *Ridging, *Soil temperature, *Soil water, *Tillage, Field tests, Model testing, Ridged soils.

Study of ridge-tillage effects on the soil environment has been impeded by the lack of models to describe adequately water and heat movement in the ridge system. The ridge system introduces many nonuniform characteristics into the field problem, such as variable solar radiation across the soil surface, unevenly distributed surface mulches, and variable water and heat transport properties caused by ridge construction or wheel traffic. A finite-element model was developed to simulate coupled water and heat flow in ridge systems. The finite-element solution scheme was chosen because of the ease by which nonuniform soil transport properties and nonuniform boundary conditions can be included in the problem specifications. Model predictions of soil water and temperature were compared with field measurements for two ridge configurations. Predicted and measured average daily temperatures over a 10-d period were within 1 C and water contents were within 0.02 cu m/cu m for 80% of the measurements. (Author's abstract)

WATER-DROP KINETIC ENERGY EFFECT ON INFILTRATION IN SODIUM-CALCIUM-MAGNESIUM SOILS.
Agricultural Research Organization, Bet-Dagan (Israel). Inst. of Soils and Water.
R. Keren.
Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 983-987, July/August 1990. 4 fig, 30 ref. U.S.-Israel Binational Agric. Res. and Development Fund Grant I-743-84.

Descriptors: *Fluid drops, *Infiltration rate, *Ions, *Rainfall impact, *Rainfall infiltration, *Soil water, Calcium, Kinetic energy, Magnesium, Simulated rainfall, Sodium, Soil aggregates, Soil chemistry, Soil types, Surface sealing.

The effect of complementary adsorbed ion (Ca vs. Mg) in the presence of Na on seal formation and water infiltration in two soils (Calcic Haploxeralf and Typic Rhodoxeralf) at several kinetic energies of water drops was studied using rain simulators. The infiltration rate (IR) of the soils was lower for the Na-Mg soils than for the Na-Ca soils at the studied kinetic energy range of the water drops (3.2-22.9 kJ/cu m). The higher the kinetic energy, the steeper the drop in IR. The steady-state IR and the cumulative water depth required to reach steady-state IR were both decreased with increasing kinetic energy of the water drops. Adsorbed Mg on montmorillonitic soils had a specific effect on IR whether or not the soil contained calcium carbonate. Aggregates with adsorbed Na and Ca ions were more stable than those with adsorbed Na and Mg ions when they were exposed to water drops having a kinetic energy in the range of 8.0 to 12.5 kJ/cu m. The specific effect of Mg on IR was explained by the presence of Mg ions on the external surfaces of the clay tactoids and the larger hydration shell of the Mg ion compared to Ca. (Author's abstract)

WATER DROPLET ENERGY AND SOIL AMENDMENTS: EFFECT ON INFILTRATION AND EROSION.
Soil and Irrigation Research Inst., Pretoria (South Africa).
H. J. C. Smith, G. J. Levy, and I. Shainberg.
Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 1084-1087, July/August 1990. 4 fig, 2 tab, 20 ref.

Descriptors: *Erosion control, *Fluid drops, *Infiltration rate, *Rainfall impact, *Rainfall infiltration, *Soil amendments, *Soil erosion, *Soil water, Electrolytes, Kinetic energy, Simulated rainfall, Surface sealing, Water quality.

The impact energy of water droplets from rain or overhead sprinklers can cause a seal to form at the soil surface. This constitutes a severe problem in agricultural lands in the arid and semiarid regions. Spreading a soil conditioner on the surface of the soil and providing a constant source of electrolytes may prevent seal formation. The effect of droplet impact energy and water quality on infiltration and erosion was studied, using a tank drip-type rain simulator, in a sandy loam soil (Typic Rhodoxeralf) treated with an anionic polyacrylamide (PAM) and phosphogypsum. Three kinetic energies of 3-mm diameter drops were obtained by varying their falling heights. The two qualities of water were distilled water and tap water, to simulate rain and irrigation water, respectively. Increasing the impact energy reduced the infiltration rate (IR), cumulative infiltration (rain intake), and soil erosion in all treatments. Addition of PAM in the presence of electrolytes (either phosphogypsum or tap water) increased both final IR and cumulative infiltration by 7-fold to 8-fold compared to the control, and was much more effective than PAM, phosphogypsum or tap water alone. The PAM plus electrolyte treatments decreased soil erosion by more than one order of magnitude compared with the control. (Author's abstract)

MACROPOROSITY AND ITS RELATION TO SATURATED HYDRAULIC CONDUCTIVITY UNDER DIFFERENT TILLAGE PRACTICES.
Minnesota Univ., St. Paul. Dept. of Soil Science
S. D. Logsdon, R. R. Allmaras, L. Wu, J. B. Swan and G. W. Randall.
Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 1096-1101, July/August 1990. fig, 4 tab, 22 ref.

Descriptors: *Hydraulic conductivity, *Porosity, *Soil water, *Tillage, Analytical methods, Infiltration, Macropores, Minnesota, Pore size, Soil texture, Soil types, Wisconsin.

Tillage management influences the distribution of macropores (biopores, cracks, interpedal planes and packing voids) that may provide pathways for rapid infiltration of water. To aid in predicting ranges of saturated hydraulic conductivity (Ksat), macropore distribution in situ was characterized by exposing selected horizontal planes and tracing macropores on clear polyethylene sheets. A methylene blue solution was used to indicate macropore continuity through the pressure pan. Sixteen undisturbed cores were taken in a grid pattern from each Ap horizon and adjacent subsoil for determination of Ksat. Field marking on plastic sheets was superior to photographic slides as a technique to characterize macropores because film noise (fine pores) was eliminated, overall analysis time was reduced, and different features could be separated for analysis. However, a bias of pore size between observers was possible. Four sites in southern Minnesota and Wisconsin with four different soil series were examined. Below the maximum tillage depth, macropores were present at all locations, but tillage disrupted continuity of pores from the surface. No-till had macropores throughout the upper 30 cm with continuity observed in the 0-35 cm range. Numbers of pores >0.4 mm diam/sq m ranged from 100 to >3,000, representing 0.1 to 2% of total area. When present, horizontal crack length ranged from 1.7 to 19.3 m/sq m. Measured Ksat of undisturbed detached cores ranged from 1.1 to 1 microm/s with CVs ranging from 44 to 197%. Ksat could be estimated within a range (out of eight classes) from descriptions of biopore, cracks, soil structure, and soil texture. (Author's abstract)

SOIL WATER DIFFUSIVITY DETERMINATION BY A MODIFIED ONE-STEP OUTFLOW METHOD.
Nebraska Univ.-Lincoln. Dept. of Agronomy.
S. Mu'azu, J. Skopp, and D. Swartzendruber.
Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 1184-1186, July/August 1990. fig, 11 ref.

Descriptors: *Analytical methods, *Diffusivity, *Hydraulic conductivity, *Mathematical analysis, *Soil water, Aeration zone, Estimating equations, Mathematical equations, One-step outflow procedures, Soil cores.

One-step outflow procedures represent potentially rapid and convenient procedures to obtain soil water diffusivity and unsaturated hydraulic conductivity data. Modifications of the existing procedures that improve and simplify the estimation of the soil water diffusivity and associated water content were derived. An equation was derived that describes the soil water diffusivity as a function of average soil water content rather than the water content at the top end of the soil core. The equation may be used over a range of water contents. The modifications presented provide a simpler analysis that is more readily applied to one-step outflow experiments. (Author's abstract)

UNSATURATED HYDRAULIC CONDUCTIVITY DETERMINED BY THE HOT AIR METHOD FOR SOME DANISH TILL SOILS.
Department of Soil Tillage, Soil Physics and Irrigation, Tinglev (Denmark).
H. Jacobsen, and H. E. Jensen.
Nordic Hydrology NOHYBB, Vol. 21, No. 2, p 129-140, 1990. 3 fig, 1 tab, 10 ref.

Descriptors: *Analytical methods, *Denmark, *Hydraulic conductivity, *Soil water, *Till, *Unsaturated flow, Aeration zone, Pore pressure, Pore water, Subsoil, Topsoil.

Many soil water transport processes such as infiltration, soil water redistribution, uptake of water by plants, and evapotranspiration involve flow in unsaturated soil. Hydraulic conductivity as a function of soil water content is one of the most important relations for successful simulation of unsaturated flow. Unsaturated hydraulic conductivity relations for topsoil and subsoil in 12 Danish till soils were obtained from measurements by the hot air method. The hot air method is simple, quick, and inexpensive to carry out, and it is applicable to a large range of soil water contents than most other experimental methods. In the range of pressure potentials within which the method is most suitable (pF values from 1.7 to 3.0) the hydraulic conductivities were found to be within the range of ten to the minus tenth power to ten to the minus seventh power m/s for topsoils, and ten to the minus eighth power to ten to the minus eighth power for subsoils. The hydraulic conductivity relations obtained may be related to the corresponding pF curves. At any pF-value the subsoils differed more than the topsoils in hydraulic conductivity. METHODS USED FOR CALCULATION OF PLANT AVAILABLE WATER IN NORDIC SOILS.
Copenhagen Univ. (Denmark).
B. Madsen, H. Riley, and L. Lundin.
Nordic Hydrology NOHYBB, Vol. 21, No. 2, p 111-122, 1990. 4 fig, 4 tab, 32 ref.

Descriptors: *Analytical methods, *Soil moisture retention, *Soil water, *Soil-water-plant relationships, *Till, Available water, Field capacity, Plant water potential, Soil horizons, Soil water potential.

Almost all of the Nordic countries were covered by ice during the last ice age, and most of the land is covered by till, glaciofluvial sediments, and marine deposits. The storage capacity of a soil for water available for plant production is termed the root zone capacity (RZC). Three different methods of calculating the RZC for Nordic tills have been evaluated using existing published data. Calculation of the RZC utilizes the soil water retention curve for a particular till, using the field capacity and the permanent wilting point to calculate the available water content (AWC). The AWC is then combined with the root density of different soil horizons to calculate the RZC, using one of several methods. The first method calculates the AWC within an effective root depth, and is a crude indicator of the plant-available water content in the root zone. The technique is useful for transforming soil maps into RZC maps, because the data requirements are low and mean values are used, but it is not very accurate for calculating the RZC on single profiles. The second method of calculating RZC calculates the sum of water actually used by plants from different soil layers; this method requires data from the entire soil water retention curve, and very few investigations of this type have been carried out in the Nordic countries. The third method of calculating RZC uses the simulation model HEIMDAL. The model assumes that the state of water in the soil-plant-atmosphere system can be quantitatively characterized at any moment, and that changes in the system can be described by equations. Laboratory-derived parameters for soils and plants are combined with climatic factors to calculate a variety of outputs, including summed up transpiration and the soil water status at wilting. This method requires very large amounts of data and provides very detailed information for single profiles. (Tappert-PTT)

During the first three months of the rainy season of 1987, the evolution of neutron moisture profiles was observed under traditional crops and under bare soil. The temporal variations of water storage were calculated from these measurements at two sites (at Gampela, Burkina Faso). Interesting comparisons could be made concerning infiltration, retention, and drying of the soil profiles. During the period of observation the wetting front reached a depth of 150 cm under the cultivated plot but did not penetrate farther than 50 cm under bare soil. Moreover, in less than 3 wk after the last rain the quantities of water stored in the two profiles were reduced to their initial values observed at the end of the dry season. In semi-arid regions of Africa, where rainfall variability is often large, plant-available water, which is estimated by water balance procedures, is a primary determinant of crop yields. Characterization of soil hydraulic properties is important for modeling drainage, a component of the water balance that is often ignored. Water balance studies of pearl millet were conducted in Niger from 1984-1987 on four soil types: a sand, a loamy sand, a sandy loam, and a loam. Soil samples were collected at 0.3 m depth increments from the surface to 2.1 m. Laboratory measurements of the soil moisture retention (SMR) curve were made. Saturated hydraulic conductivities were measured and combined with SMR curves to calculate unsaturated hydraulic conductivity functions. These hydraulic properties then were used in a simulation model to calculate drainage, which was different for the four soil types. With the aid of a drainage model, this study demonstrated that the drainage component in the water balance can be significant, even in years of adequate rainfall. Even for soils with a higher clay content, drainage losses could be large on a seasonal basis. Hence, water balance studies should either measure or calculate the drainage component. RELATING SOIL COLOR TO SOIL WATER TABLE LEVELS.
Ohio State Univ., Columbus. Dept. of Agronomy.
W. R. Guertal, and G. F. Hall.
Ohio Journal of Science OJSCA9, Vol. 90, No. 4, p 118-124, September 1990. 6 fig, 1 tab, 21 ref.

Descriptors: *Soil color, *Soil properties, *Soil water table, *Water table, Drainage, Ohio, Seasonal variation, Soil profiles, Soil saturation, Soil water, Water table fluctuations, Water table profiles.

Seasonal incidence of water tables in soils is one of the most important characteristics influencing their use and management. The relationship between depth to the water table and soil color was studied on a glacial till plain toposequence containing three soils (Blount, Glynwood and Morley) representative of those common throughout northwestern Ohio. As the soil drainage class changed from well drained to moderately well drained to somewhat poorly drained, the depth to low chroma colors decreased. The Morley soil had no low chroma (less than or equal to 2) colors except in the surface, where they were the result of organic matter accumulation. The Glynwood soil had low chroma colors beginning 37 cm below the soil surface, and the Blount soil had low chroma colors 28 cm below the soil surface. Low chroma mottles were the most abundant in the Blount soil profile. Decreasing depth to low chroma colors can be related to changes in the soil water table levels. The results suggested that gray colors (chroma of less than or equal to 2) in mottles indicate that the horizon is near or just above the water table level. If the horizon is dominated by gray colors (gleyed) in the soil matrix, then that horizon is saturated much of the time. It can be concluded that the presence of colors of 2 chroma or less reliably predicts the depth to the water table. (MacKeen-PTT)

The topography of the Appalachian region strongly influences the environment for plant growth. A field study was conducted in 1984 and 1985 on a Gilpin silt loam in West Virginia to determine soil and environmental factors controlling corn (Zea mays L.) yield differences among landscape positions. Four plots were established at each of 9 locations including summit, shoulder (N. E. S. W. aspects) and backslope (N. E. S. W. aspects). Although common management practices were used throughout the field, corn yields varied significantly among positions. Mean 'available water' as represented by the difference between gravimetric water determined over time and water retained at 1500 kPa, was the most important factor controlling corn production. The objectives of this study were to determine the relationship between soil physical properties, surface curvature, and precipitation catch on the distribution of soil water, with emphasis on the surface layer (0-15 cm depth). Available water was always lower at the backslope sites than at the summer or shoulder sites. Higher clay content and lower infiltration capacity were associated with lower available water. Precipitation catch differences strictly followed the same pattern as available water between shoulder sites and summit. A cokriging analysis indicated that surface curvature may be useful for spatial representation of available water throughout the study site. (Author's abstract)

T. Brandyk, and R. Romanowicz.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 19-28, 5 fig, 9 ref.

Descriptors: *Aeration zone, *Model studies, *Soil water, *Soil-water-plant relationships, Control systems, Decision making, Flow control, Hydraulic conductivity, Hydrologic models, Mathematical models, Root zone, Shallow aquifers, Soil moisture deficiency, Soil moisture retention.

Soil moisture control for soils with shallow groundwater levels is necessary to maintain the required moisture content in the root zone of the vegetation. Water management in the plant root zone requires a knowledge of the actual soil moisture content. Mathematical models based on the application of steady and unsteady soil moisture theory can be very helpful in this regard. Both steady and unsteady state soil moisture models of the unsaturated zone with an analytical exponential unsaturated hydraulic conductivity function were considered. The long-term soil moisture control problem was formulated using steady state soil moisture theory. In this case the typical control problem has an open-loop control structure. The short-term soil moisture control problem was formulated using unsteady state soil moisture theory. In this case it is possible to develop a closed-loop control structure. The long-term control concept was confirmed by field measurements of soil moisture pressure heads and numerical simulation of unsteady state soil moisture flow. Due to the very complex form of the analytical solution of the unsteady state model its further linearization should be performed. This would allow development of closed-loop control algorithms for the short-term moisture control problem. (See also W91-02672) (Fish-PTT)

CALIBRATION OF TIME DOMAIN REFLECTOMETRY FOR WATER CONTENT MEASUREMENT USING A COMPOSITE DIELECTRIC APPROACH.
Eidgenoessische Technische Hochschule, Zurich (Switzerland).
K. Roth, R. Schulin, H. Fluhler, and W. Attinger.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2267-2273, October 1990. 4 fig, 2 tab, 21 ref.

Descriptors: *Electrical properties, *Instrumentation, *Measuring techniques, *Soil moisture meters, *Soil water, *Soil water potential, *Time domain reflectometry, Calibrations, Mathematical models, Neutron scattering, Regression analysis, Sensitivity analysis.

Time domain reflectometry (TDR) has been developed to an operational level for the measurement of soil water content during the past decade. TDR has become an alternative to the neutron scattering method because it provides fast, precise and nondestructive in situ measurements. One of the major disadvantages of the neutron scattering technique is that, due to the relatively high sensitivity of the signal to factors other than water content, site specific calibration is usually required. A calibration curve is developed for the TDR method which is not restricted to specific soil conditions. The calibration is based on a dielectric mixing model. Measurements of volumetric water content and dielectric number at eleven different field sites representing a wide range of soil types were used to determine the parameter of the model by weighted nonlinear regression. The uncertainty (root mean square error) of water content values calculated with the optimized calibration curve was estimated not to exceed 0.013 cc/cc. This value is comparable to the precision of the thermogravimetric method. From a sensitivity analysis the temperature dependence of the TDR signal may have to be corrected to obtain optimum accuracy. (Author's abstract)

COMPUTER-CONTROLLED 36-CHANNEL TIME DOMAIN REFLECTOMETRY SYSTEM FOR MONITORING SOIL WATER CONTENTS.
Amsterdam Univ. (Netherlands). Lab. for Physical Geography and Soil Science.
T. J. Heimovaara, and W. Bouten.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2311-2316, October 1990. 5 fig, 14 ref.

Descriptors: *Automation, *Measuring instruments, *Reflectance techniques, *Soil moisture meters, *Soil water, *Time domain reflectometry, Computer programs, Precision, Spatial distribution, Temporal distribution.

Research on the spatial and temporal dynamics of soil water has long been impeded by the lack of an automated technique for the measurement of soil water content. A computer controlled time domain reflectometry (TDR) system makes a large number of measurements at different sites at predetermined time intervals possible. The system operates on 12 V dc and has the capability to monitor water content at 36 sites. The TDR element of the system is the TEKTRONIX 1502B metallic TDR cable tester, connected to the transmission line probes through a 36-channel coaxial relay. The system is controlled by a Pascal program which obtains the TDR wave forms required for calculating water content. The algorithm used for the automatic analysis of the measurements is based on the calculation of the travel time of the TDR signal between the beginning and the end of a three-rod probe. Quantification of the resolution of the 1502B cable tester is very difficult. Increasing the measurement frequency may be a means of filtering out noise and improving the precision of the method. SOLUTION OF A NONLINEAR ABSORPTION MODEL OF MIXED SATURATED-UNSATURATED FLOW.
La Trobe Univ., Bundoora (Australia). Dept. of Mathematics.

P. Broadbridge.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2435-2443, October 1990. 4 fig, 22 ref, append.

Descriptors: *Absorption, *Groundwater movement, *Hydrologic models, *Saturated flow, *Saturation zone, *Soil water, *Unsaturated flow, Gravity, Heterogeneity, Mathematical models, Ponding.

In wetted soils, zones of saturation develop naturally in the vicinity of impermeable strata, surface ponds, and subterranean cavities. A nonlinear diffusion model of Fujita is adapted to solve a mixed saturated-unsaturated flow problem representing absorption of water by a soil with a constant pond epth at the surface. From the closed-form solution, an equation emerges which relates dimensionless sorptivity, dimensionless pond depth, and a ngle soil hydraulic nonlinearity parameter. For he whole range of soil types, the ratio of ponded orptivity to unponded sorptivity increases significantly with pond depth but the ponding effect is ronger in weakly nonlinear soils than in highly onlinear soils. In weakly nonlinear soils the pond- g effect is greatly enhanced by increasing the itial water content, but in extremely nonlinear ils the initial water content has little influence. he gravity-free ponded model, could be the foun- tion for other more sophisticated models which corporate gravity or heterogeneity. prediction of the distribution of water and tes in the soil medium is essential for both ient agricultural practice and for controlling quality of subsurface water. Uncertainty propa- on with numerical models for flow and trans- in the unsaturated zone is studied using vector -space methods. The output uncertainty is the t of spatially, randomly varying parameters ribing the soil hydraulic properties. An effi- state covariance propagation method is pro- d, based on first-order linearization of the m dynamics. The approach has been previous- ed with groundwater flow models, and com- ons are made with a Monte Carlo simulation iltration in two soils with distinctly different roperties. For coefficients of variation of the neters less than 0.3 the two methods agree The linearization method is found to be faster o its analytical nature. The results are a first for future research on parameter estimation, the state-space linearization approach. (Au- abstract)

OBILE WATER DURING SOLUTE SPORT IN UNSATURATED SAND COL- S.
ionwealth Scientific and Industrial Research ization, Canberra (Australia). Div. of Soils.
Bond, and P. J. Wierenga.
Resources Research WRERAQ, Vol. 26,), p 2475-2481, October 1990. 2 fig, 2 tab, 24 pend. NRC project No. TD-2049 and EPA No. R-811862-02-0.

ptors: *Aeration zone, *Sand, *Soil col- *Soil water, *Solute transport, *Unsaturated Flow pattern, Flow rates, Interstitial water, flow, Unsteady flow.

The existence of preferential pathways for the flow of water through soils affects not only the distribution of water in the soil but also the distribution of solutes. Solute transport experiments examined the presence of immobile water in an unsaturated fine sand under different flow regimes. Both steady and unsteady flow conditions were imposed, but the average pore water velocity and water content were the same in each treatment. Evidence for the presence of an immobile water fraction was sought by fitting the concentration distributions using models both with and without an explicit term accounting for solute exchange with immobile water. Strong evidence was found for the presence of an immobile water fraction affecting the solute concentration distribution under steady flow conditions but not for unsteady flow. These apparently conflicting results are explained by the different water flow patterns arising from the two flow regimes, and suggest that care is needed when extrapolating the results of experiments carried out under one flow regime to a different flow regime. MODELING INFILTRATION INTO A SEALING SOIL.
Texas Agricultural Experiment Station, Lubbock.
R. I. Baumhardt, M. J. M. Romkens, F. D. Whisler, and J. Y. Parlange.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2497-2505, October 1990. 7 fig, 4 tab, 27 ref.

Descriptors: *Hydraulic conductivity, *Infiltration, *Mathematical models, *Saturated flow, *Soil porosity, *Soil sealants, Rainfall intensity, Soil properties, Unsaturated flow.

Rain infiltration is often controlled by a less permeable layer known as a seal. An important consideration in modeling infiltration into a sealing soil is the requirement of describing changes over time in both the saturated and unsaturated hydraulic conductivity of the surface. Infiltration through this layer was modeled numerically using a numerical model based on the Richard's equation with an algorithm which continuously updating the seal properties (saturated hydraulic conductivity, porosity, water entry value, specific water capacity) as a function of rainfall characteristics. The seal remains unchanged until the surface has reached incipient ponding. Subsequently, a rapid change in the hydraulic properties of the seal is imposed to reflect the effect of raindrop impact. Finally, an equilibrium state develops between seal formulation due to raindrop impact and seal erosion due to the rainstorm intensity effects. Model-predicted infiltration was similar to that observed during simulated rainstorms having various combinations of intensities and kinetic energy rates per millimeter of rain. A sensitivity analysis was performed to determine the effects of changes in seal and bulk soil properties, as well as simulation parameters, on infiltration. Seal formation was dependent on cumulative rainfall energy and the rainstorm intensity. (Author's abstract)

Water Resources Research WRERAQ, Vol. 26, No. 10, p 2563-2578, October 1990. 8 fig, 1 tab, 56 ref, append.

Descriptors: *Adsorption, *Equilibrium, *Groundwater movement, *Path of pollutants, *Soil chemistry, *Soil porosity, *Soil water, *Solute transport, Kinetics, Mathematical models, Sorption, Traveling wave, Wave velocity.

Transport was modeled for a soil with dual porosity, or with chemical nonequilibrium, assuming first-order kinetics. The equilibrium sorption equation in the immobile region is nonlinear. The Langmuir and the Van Bemmelen-Freundlich equations were considered for sorption. The sorption equation in the mobile region is assumed to be linear. Analytical solutions were obtained for the traveling wave displacement found for initial resident concentrations that are smaller than the feed concentrations and for infinite displacement times, neglecting the coupled effects of dispersion and nonequilibrium conditions. These waves travel with a fixed shape and a fixed velocity through the homogeneous flow domain. Differences with respect to the linear sorption case are the smaller front thickness and the non-Fickian type of displacement. The non-Fickian behavior is intrinsic to the traveling wave assumption as the front does not spread with the square root of time. The analytical solutions obtained for the equilibrium and for the nonequilibrium situations are mathematically equivalent. Only the effective diffusion/dispersion coefficient needs to be adapted to account for nonequilibrium effects, as for linear dual-porosity models. Apart from early time behavior, the traveling wave solutions agree well with numerical approximations. The front steepness depends on the degree of nonlinearity. The sensitivity on the dispersion coefficient and first-order rate coefficient may be large but depends on which mechanism controls front spreading. (Author's abstract)

RECIPROCAL DIEL VERTICAL MIGRATION BEHAVIOR IN PLANKTIVORES AND ZOOPLANKTON IN BRITISH COLUMBIA LAKES.
Department of Fisheries and Oceans, Vancouver (British Columbia). West Vancouver Lab.
D. A. Levy.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 9, p 1755-1764, September 1990. 7 fig, 51 ref.

Descriptors: *Crustaceans, *Diurnal variation, *Ecosystems, *Fish behavior, *Lakes, *Limnology, *Migration, *Predation, *Salmon, *Vertical distribution, *Zooplankton, British Columbia.

Simultaneous comparison of planktivore and crustacean zooplankton distribution patterns in a set of British Columbia lakes suggested coupled diel vertical migration behavior in the two adjacent trophic levels. In lakes where juvenile sockeye salmon performed diel vertical migrations, most zooplankton were non-migratory and concentrated in shallow surface waters over the diel cycle. In contrast, in one lake where pelagic threespine sticklebacks were present, and where juvenile sockeye diel

vertical migrations were periodically reversed, most zooplankton undertook diel vertical migrations. The presence of diel vertical migration behavior in zooplankton thus appears to be related to the presence or absence of the behavior in the predominant planktivores. (Author's abstract)

Descriptors: *Eel, *Fishkill, *Great Lakes, *Lamprey, *Streambeds, Correlation analysis, Discriminant analysis, Gravel, Sand, Substrates, Water temperature.

The sea lamprey is of economic importance to the Great Lakes because it parasitizes salmonids and other game species resulting in significant mortality. The effect of 14 environmental variables on the occurrence of sea lamprey (Petromyzon marinus) ammocoetes was examined in 73 tributaries of the Great Lakes. We successfully classified 86% of streams without lamprey and 90.5% of streams with ammocoete populations using discriminant analysis. Eighty percent of streams in a test data set were also successfully classified. The classification success was largely determined by differences in stream substrate characteristics based on the magnitude of canonical coefficients and contribution to the multivariate F-statistic. Streams with ammocoetes had a significantly ($P < 0.10$) higher proportion of sand and a lower proportion of bedrock and clay than streams without ammocoetes. Catch per unit effort of ammocoetes collected with electrofishing gear was also significantly related ($P = 0.004$) to the proportion of rubble, gravel, and clay. A significant ($P < 0.01$) positive relationship existed between conductivity and temperature with size of 2+ ammocoetes. Results indicate that predictions could be developed for the number of metamorphosing ammocoetes based upon substrate differences in stream characteristics. (Author's abstract)

Techniques have been developed for the measurement of bacterial production (by the rate of tritiated thymidine and disturbance artifacts (TdR) incorporation into DNA), isotope dilution, time course of incorporation of nucleoside, and disturbance artifacts in natural epilithic communities of headwater streams. The epilithon in riffles was subsampled by carefully chipping upper rock surfaces. Chips were placed in test tubes and incubated in situ. Test tubes were rotated to reduce the formation of artificial diffusion barriers to TdR transport. DNA was isolated using a double filtration technique. Summertime production had a range of 1.3 to 51 mg carbon/sq m/hr in five southern Ontario streams. Precursors to DNA synthesis, which diluted tritiated TdR, had a range of 63 to 440 nM. Incorporation of tritiated TdR was linear for at least one hour. Disturbance artifacts did not appear from rock chipping or from extended sample rotation. The techniques can be applied to other microbial groups from various aquatic hard substrata. (Author's abstract)

Descriptors: *Aquatic bacteria, *Bacteria, *Food chains, *Lake Michigan, *Limnology, *Plankton, Bacterial physiology, Growth rates, Organic carbon, Predation, Substrates.

The roles of both heterotrophic and autotrophic picoplankton in aquatic food webs are increasingly recognized as ecologically important. Lake Michigan epilimnetic heterotrophic bacterial loss rates, predator size, and substrate limitation was estimated in 1986 and 1987. The bacterial growth rates were always enhanced by organic substrate additions indicating that bacterial growth is limited, to some degree, by substrate availability. Loss rates and growth rates between 0.32 and 1.45 per day were obtained. The grazers were predominantly picoplankton-size organisms, presumably heterotrophic flagellates. Using radiolabeled bacteria, only a small percentage (2 to 3%) of bacterial cells were incorporated into larger size fractions after 24 hours. These results indicate that heterotrophic bacteria were not a direct, significant, carbon source for the upper trophic levels. (Author's abstract)

Alewife abundances declined dramatically in southeastern Lake Michigan over 1973 to 1977, several years before the lakewide decline occurred. The regional effects of this decline on adult copepod abundances, zooplankton biomass, and water clarity were investigated. In the offshore region, the two largest copepods, Limnocalanus macrurus and Diaptomus sicilus, increased in abundance during the mid-1970's reflecting the decrease in alewife predation. L. macrurus abundances declined in later years, reflecting increased predation pressures from the increasing bloater population. The small-bodied D. minutus and the medium-bodied D. ashlandi exhibited no apparent response to the decline in alewife abundance. Large-bodied D. oregonensis and small-bodied Calanus bicuspidatus thomasi declined in abundance. Size-selective fish predation pressures continued to remain high in the inshore region; increased abundance of yellow perch and rainbow smelt apparently compensated for the alewife decline. Zooplankton biomass, zooplankton mean dry weight, and water clarity apparently were not affected by the decline in alewife abundance in either the inshore or offshore regions. The results were evaluated in terms of the lakewide decline in alewife abundance, the summer 1983 dominance of Daphnia pulicaria in offshore waters, the 1983 marked improvement in offshore water clarity, and later changes in summer offshore D. pulicaria populations, and suggest that phytoplankton control strategies should not be based solely on top-down management strategies. Moreover, top-down management strategies are probably more useful for moderately productive than for eutrophic systems and for small lakes rather than large and ecologically complex systems such as the Great Lakes. A model which was developed and calibrated for predicting algal growth in mass cultures was modified for natural systems. In turbid systems, the ratio of euphotic to aphotic depth is usually small and mixing may exceed the compensation depth in order to compensate for the various light regimes to which the phytoplankton would be subjected. the losses due to dark respiration were modified that the effective light history would determine actual rate. The efficiency of light utilization changes under different light regimes and the model was modified to take these variations into account. Both of these modifications resulted different production profiles being generated the same surface conditions, but with different mixing depths, where the phytoplankton became more efficient as the light regime deteriorated less respiration and greater light utilization efficiency). A further consequence is that the 'critical mixing depth' is approximately 2.5 times greater than that which was previously accepted, namely about 20 times the euphotic depth. The model predicted productivities to within 90% of observed rates. The predictions could also be used to determine the extent of nutrient limitation. The predictions have biomanipulatory consequences, as variations of the light regime through the additional non-photosynthesizing materials, under certain conditions, may even result in a stimulation of phytoplankton productivity. Descriptors: *Acid rain effects, *Acidity, *Animal behavior, *Aquatic animals, *Light effects, *Limnology, *Temperature effects, Daphnia, Genotypes, Hydrogen ion concentration, Phototaxis, Thermal stress, Water temperature, Waterfleas.

The influence of culture temperature, temperature shocks and pH shocks on the phototactic behavior of four Daphnia magna clones was studied. Test animals tended to become more positively phototactic when the pH of the medium was raised, in the pH range of 6 to 9. D. magna clones were less positively phototactic when cultured at high (27 C) temperature. Responses to temperature changes at the start of the experiment were clone-dependent. Only substantial temperature shocks (>10 C) seemed to alter the phototactic behavior significantly. Differences between genotypes remained highly significant despite the broader environmental conditions in which experiments were carried out. Broad heritability estimates for the phototactic behavior of Daphnia under the different environmental conditions studied ranged from 0.78 to 0.88. (Author's abstract)

DIEL AND SEASONAL ENERGY TRANSFER, STORAGE AND STRATIFICATION IN AFRICAN RESERVOIRS AND LAKES.
Freshwater Biological Association, Ambleside (England).
J. F. Talling.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 651-660, 1990. 5 fig, 34 ref.

Descriptors: *Africa, *Energy transfer, *Heat storage, *Lakes, *Limnology, *Reservoirs, *Thermal stratification, Diurnal variation, Humidity, Lake evaporation, Seasonal variation, Tropical regions, Water temperature.

Relationships between water temperature, heat storage, and other components of the energy budget for African reservoirs and lakes were surveyed. The seasonal variations of surface temperature and incident short-wave solar radiation are broadly correlated in a latitudinal series, with minimum amplitude and phase reversal near the equator. Some divergences can be related to changes of the evaporative (latent heat) flux density, conditioned by seasonally altered humidity and wind regime. Within the tropics there is a close relationship between bottom temperature and altitude, as yet unsupported by finer physical analysis. The resolution of component flux densities in the diel energy budget is illustrated by three examples from work on Lake Chad and a Nile reservoir. For the latter, the residual ascribed to diel heat storage was broadly consistent with observed rates of heat storage, although these also suffered irregularities from horizontal advection. Such diel heat storage is ecologically influential, through induced thermal stratification, in many African water bodies. Its magnitude is compared, across a range of latitudes, with the much larger amplitude of annual heat storage. (Author's abstract)

LIMNOLOGY AND EUTROPHICATION OF BARRA BONITA RESERVOIR, S. PAULO STATE, SOUTHERN BRAZIL.
Sao Paulo Univ., Sao Carlos (Brazil). Escola de Engenharia.
J. G. Tundisi, and T. Matsumura-Tundisi.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 661-676, 1990. 16 fig, 26 ref.

Descriptors: *Barra Bonita Reservoir, *Brazil, *Eutrophication, *Limnology, *Phytoplankton, *Reservoirs, *Water pollution effects, *Zooplankton, Chlorophyll, Flushing, Nitrogen, Phosphorus, Primary productivity, Rainfall, Reservoir sediments, Residence time, Thermal stratification, Wind.

Limnological studies coupled with climatological measurements were made in the Barra Bonita reservoir, Brazil. One year of sampling showed a pattern in which main forcing functions were rainfall, wind, flushing rate, and residence time. Summer months were characterized by short water residence time (one month) while in the autumn, winter and spring periods the residence time was higher (six months). The seasonal cycle of phytoplankton biomass and composition, primary production and nutrient cycles are controlled by the coupling of the above four factors. The reservoir is polymictic with short periods of stratification. Primary production ranges from 200 to 800 mg C/sq m/day. The phytoplankton change from a flagellate/diatom community to a diatom/blue green one during periods of long residence time. Chlorophyll values range from 5 to 238 micrograms/L during heavy blooms. Concentration of phosphorus is maintained at low levels due to continuous circulation and precipitation to the sediment. Nitrogen is not limiting for phytoplankton production. Cyclopoida dominate over the Calanoida in the zooplankton community, a fact that confirms the eutrophic nature of the reservoir. Adequate treatment along with the introduction of periods with lower or higher discharge coupled with the hydrologic cycle and flushing rate is an important step in the management of this reservoir. Nutrient reduction could also be achieved by aeration of the tributaries that are major sources of P inflow, increasing the through-flow of spill water during the rainy season thus eliminating possible phytoplankton concentrations, and introducing artificial mixing in the main channel. Other techniques would include reduction of the bottom deposits of sediments and organic matter at intake structures for the turbines in deep water, and land use practices such as protection zones, application of fertilizers, crop rotation, and spoil stabilizing tillage techniques. (Author's abstract)

ANNUAL AND LONGITUDINAL CHANGES IN THE ENVIRONMENTAL CONDITIONS IN THREE CONSECUTIVE RESERVOIRS OF THE GUADIANA RIVER (W. SPAIN).
Barcelona Univ. (Spain). Dept. de Ecologia.
J. Armengol, F. Sabater, J. L. Rierra, and J. A. Morgui.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 679-687, 1990. 4 fig, 2 tab, 15 ref. Comision Aserora de Investigation Cientifico y Tecnica, Programa PB85-0166.

Descriptors: *Environmental gradient, *Guadiana River, *Limnology, *Multireservoir networks, *Reservoirs, *Spain, Alkalinity, Chemical properties, Chlorides, Chlorophyll a, Conductivity, Flow, Hydrogen ion concentration, Nitrates, Nitrites, Oxygen, Phosphates, Physical properties, Principal component analysis, Seasonal variation, Secchi disks, Sulfides, Water temperature.

Temporal and longitudinal changes in the environmental conditions in a cascade of three reservoirs on the Guadiana River (Spain) were studied. Physical and chemical parameters were used to characterize longitudinal patterns of change: conductivity, Secchi disk, pH, alkalinity, temperature, oxygen, nitrate, nitrite, phosphate, chloride, sulfide, monthly water, flow volume, water speed and chlorophyll a. Temporal heterogeneity along two years with different climatic conditions was also considered. By means of principal component analysis (PCA) a gradient analysis was performed using the scores of each sampling point in the space defined by the first three principal axes. The first principal component axis was strongly correlated with a group of variables that jointly determine the salinity of the water and can be simply be expressed as conductivity. In Guadiana reservoirs, salinity/conductivity are a consequence of water inputs from the endorreic upstream catchment. The variables more correlated with the second axis

were represented by water temperature and varied according to a seasonal cycle. The third principal component represented the average and annual pattern of spatial evolution produced by the combination of physical, chemical, and biological processes taking place along the main axis of the reservoirs. The results demonstrate three levels of temporal and spatial organization: (1) annual changes common to the three reservoirs--PCA axes 1 and 2, (2) differences among reservoirs--PCA axis 1, and (3) differences among stations inside each reservoir--PCA axis 3. (Author's abstract)

CLIMATE AND CLIMATIC RESOURCES OF RESERVOIRS.
Limnologicheskii Inst., Irkutsk (USSR).
N. P. Ladeishchikov, and V. A. Obolkin.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 689-693, 1990. 1 tab, 7 ref.

Descriptors: *Climatology, *Environmental effects, *Lakes, *Limnoclimatology, *Reservoirs, Air pollution, Air temperature, Heat budget, Limnology, Model studies, Precipitation, Recreation, Siberia, USSR.

A model of reservoir limnoclimate can be represented as a function of: (1) the thermal flow at the reservoir surface; (2) the thermal capacity of the reservoir; (3) the loss of heat from the reservoir surface to the atmosphere; (4) moisture exchange between the atmosphere and the lake; (5) the intensity of local circulation exchange in the reservoir's coastal zone; (6) the degree of orographic isolation; and (7) the intensity of macroadvection over the reservoir. The relative stability of a reservoir's limnoclimate stabilizes its ecological surroundings against the external influences of seasonal and secular variations of climate. Therefore, limnoclimate must be considered along with other factors in the creation and development of reservoirs. A comparison of mean air temperature and atmospheric precipitation in the region of three Siberian reservoirs before and after reservoir formation indicates that reservoirs significantly influence the climate. The reservoirs and lakes have a smoothing effect on the climate of surrounding areas, lowering the amplitude of both daily and annual temperature and precipitation variations. The climatic effect (cooling in summer) of these Siberian reservoirs causes some aggravation of atmospheric pollution over their surfaces due to an increase in inversion frequency and a decrease of topographic relief. On the other hand, reservoir areas have greater overall atmospheric clarity, less weather severity and variability, and longer-lasting periods of favorable meteorological conditions than comparable continental regions. The construction of man-made reservoirs results in a wide variety of recreation resources in both the reservoir and its surroundings. This recreational potential is enhanced by the climatic amelioration. (Sand-PTT)

LONG-TERM TRENDS IN THE SESTON CONTENT OF A SHALLOW EUTROPHIC LAKE AND SOME RELATIONS TO CLIMATIC ELEMENTS.
Institute of Geography and Geoecology, Berlin (German D.R.). Dept. of Hydrology.
R. Stellmacher.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 695-699, 1990. 2 fig, 1 tab, 10 ref.

Descriptors: *Algae, *Climatology, *Eutrophic lakes, *Limnology, *Seston, Air temperature, Germany, Lake Muggelsee, Population dynamics, Regression analysis, Seasonal variation, Thermal radiation, Time series analysis.

Seasonal time series of the buoyant part of the seston content of Lake Muggelsee, the sums of negative daily mean temperatures in Berlin, and the global radiation in Potsdam have been collected for as long as 50 years. The structure of these time series and the relationships between them were investigated. The series are characterized by more or less strong cyclic variations of from 2 to 24 years. A moving spectral estimation of daily mean temperatures gives an idea of the change of spectral behavior over time: in the past, periodicities of about 3.4, 5, and 10 years dominated, but at present there are cycles of about 2.3 and 7 years. Regression analysis showed that winter severity influences only the starting phase of algal development. It was concluded that monthly values are not sufficient to describe causal relations between seston content and the population dynamics of individual algal species; shorter average periods are necessary. However, monthly, seasonal, and annual values are useful for determining correlations between more general entities such as the buoyant part of seston and certain climatic elements. (Author's abstract)

BIOLOGICALLY AVAILABLE PHOSPHORUS RETENTION BY THE KIS-BALATON RESERVOIR.
Ulster Univ., Coleraine (Northern Ireland). Limnology Lab.
J. Zlinsky, and S. Herodek.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 703-707, 1990. 3 fig, 1 tab, 10 ref.

Descriptors: *Eutrophication, *Limnology, *Nutrient transport, *Path of pollutants, *Phosphorus, *Reservoirs, *Water pollution control, Algal blooms, Cyanophyta, Hungary, Lake Balaton, Phytoplankton, Wastewater treatment, Zala River.

The largest tributary of Lake Balaton, the River Zala, discharges 50 tons of dissolved phosphorus (DP) and 40 tons of particle-bound phosphorus (PP) per year, causing serious eutrophication of the westernmost basin of the lake. To complement other measures of water quality protection in the catchment area, the shallow reservoir Kis-Balaton was built to reduce the nutrient load and prevent silting. The changes in the concentration and relative importance of P fractions entering and leaving the reservoir were investigated. The dissolved biologically available P (BAP) concentrations usually equal the soluble reactive P (SRP). The non-reactive DP concentration remained unchanged along the river. Winter experiments showed a PP and a total dissolved P (TDP) retention of 87% and 49%, respectively, giving a total P (TP) retention of 70%. The availability of the effectively withheld PP proved to be only 17-19%, lowering the overall BAP retention to 60% of the TP. During the summer there were blue-green algal blooms in the reservoir. The P uptake of the phytoplankton increased the TDP and SRP retention to 74% and 86%, respectively, but there was more PP leaving the reservoir than entering it. At the lowest reach of the River Zala, the significant increase of dissolved BAP and PP concentrations indicates important sources of pollution. The major part of P leaving the reservoir in readily available dissolved forms originates from sewage. The contribution of diffuse P loading (like soil erosion in the watershed) to eutrophication is much less than that of the sewage plants, if judged with respect to BAP rather than to TP measurements. Eutrophication models suggest that to prevent the algal blooms, the BAP loading should be reduced by 75%. Considering the higher availability and lower retention rate of sewage P, tertiary treatment plants both upstream and downstream of the reservoir seem to be the most effective investment to achieve this goal. PELAGIC CALCITE PRECIPITATION AND TROPHIC STATE OF HARDWATER LAKES.
Akademie der Wissenschaften der DDR, Berlin. Zentralinstitut fuer Mikrobiologie und Experimentelle Therapie.
R. Koschel.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 713-722, 1990. 3 fig, 2 tab, 56 ref.

Descriptors: *Calcite precipitation, *Calcium carbonate, *Hardness, *Hardwater lakes, *Limnology, *Trophic level, Chlorophyll, Eutrophication, Germany, Phosphorus, Phytoplankton.

The CaCO3 concentration of different hardwater lakes of the Mecklenburg District was analyzed and related to trophic conditions. The results indicate that calcite precipitation is associated with coreactions which play a fundamental role in self-purification of the lakes. High calcite precipitation provides a high autochthonous self-protection potential and helps counteract eutrophication. The relation between the chlorophyll a content of the phytoplankton and the total phosphorus content is a sigmoid function in the lakes examined. This sigmoid character is lost in stratified hardwater lakes. The calcite precipitation causes the phyto plankton biomass to be reduced during the summe stagnation period. Calcite precipitation slows u eutrophication and diminishes the exponential in crease in phytoplankton biomass in relation t phosphorus supply. The regulation of trophic stat is obviously different for hardwater lakes an softwater lakes. Therefore, for lakes with a hig temporary hardness (with calcite precipitation classification of trophic state, especially in terms o the phosphorus and phytoplankton biomass, shoul be performed differently from classification those with a low temporary hardness (witho calcite precipitation). LONGITUDINAL DIFFERENTIATION AC CORDING TO ENVIRONMENTAL FACTOR AND PHYTOPLANKTON IN ARACENA AN LA MINILLA RESERVOIRS (SEVILL SPAIN).
Seville Univ. (Spain). Faculty of Biology.
J. Toja.
Ergebnisse der Limnologie ERLIA6, Vol. 33, N 3, p 733-747, 1990. 7 fig, 4 tab, 12 ref.

Descriptors: *Eutrophic lakes, *Limnology, *Ph toplankton, *Reservoirs, *Spain, Arecena Res voir, Environmental gradient, Eutrophication, Minilla Reservoir, Lake stratification.

The possible differentiation of the environmen characteristics and phytoplankton communi along the Aracena and La Minilla reservoirs studied from April 1977 to May 1978. In e reservoir five sampling stations were studied. A cena had a behavior similar to a lake and envir mental factors and phytoplankton developm both showed little difference among various zo of the reservoir. The characteristics of the sam depended on organism activity in response to p esses linked to the mixed-stratification cycle. H ever, the secondary branch of the reservoir w little more eutrophic than the primary branch, summer conditions appeared there before they at the other stations. La Minilla reservoir beha more like a river and the water flow determ the characteristics of each zone. There was a ferentiation between the environmental factor the dam and river zones, but differences in phytoplankton communities were not signific (Author's abstract)

The variability and interactions of phytopla and zooplankton over seasons and years we

rpreted from plankton samples taken at nearly eekly intervals for 11 years. The soluble reactive ncentrations of the growth-limiting nutrient osphorus underwent great variation, but no cor- ation with the phytoplankton could be detected. rong interactions were found between phyto- nkton and zooplankton. A direct and significant rrelation became evident between the maximum limnetic biomass of crustacean zooplankton and onial green algae, whose apparent indigestibility y protect them from grazing. A negative rela- nship existed between the epilimnetic biomasses Asterionella, diatoms, and nanoplankton and the stacean (Daphnia) biomass, indicating that high icentrations of herbivores are able to control se algae. No correlation could be found be- en crustacea and blue-green algae or Fragilaria. chi-disk readings showed a weak positive rela- ship to the crustacean biomass. The main result his investigation was the evidence of strong ractions between phytoplankton and zooplank- over whole seasons. (Author's abstract)

Descriptors: *France, *Lake classification, *Lake morphology, *Limnology, *Reservoirs, Cluster analysis, Correlation analysis, Factor analysis, Principal component analysis, Water quality trends.

To help forecast trends in the water quality of reservoirs, classification of 185 French reservoirs was carried out on the basis of their physical characteristics. The 22 abiotic characters used were selected according to the importance placed on them in the literature to explain the biological structure of lake ecosystems. These variables were evaluated statistically. Correlation analysis showed that these descriptive factors can be divided into five clusters: (1) factors describing inflow to the reservoir; (2) morphometric characteristics; (3) reservoir operating conditions; (4) technical specifications of the hydraulic machinery; and (5) qualitative data--catchment geology, geographic position, river regime, type of dam, reason for construction, etc. The automatic clustering of the reservoirs defines 7 principal types whose differences are explained by a multiple-correspondence factor analysis: (1) reservoirs on smaller streams, but situated far from the headwaters, and having major water-level fluctuations; (2) reservoirs on France's largest rivers, with minimal water-level fluctuations, and with current-powered generating plants; (3) deep reservoirs on the high-altitude headwaters of streams; (4) the largest reservoirs, characterized by a low water-mass renewal rate and great lake-level fluctuation; (5 and 6) reservoirs 30 to 40 m deep, situated at moderate altitudes, and having important water-level fluctuations (these two types differ from one another in the amount of their inflow); and (7) reservoirs on the headwaters of small streams. WATER QUALITY IN CZECHOSLOVAK WATER-SUPPLY IMPOUNDMENTS.
Prague Dept. of Water Technology and Environmental Engineering (Czechoslovakia).
V. Sladecek.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 819-825, 1990. 3 fig, 4 tab, 23 ref.

Descriptors: *Czechoslovakia, *Lake classification, *Limnology, *Reservoirs, *Water quality criteria, Ecosystems, Environmental effects, Pollution index, Trophic level, Water supply.

The saprobic index and the trophic potential were used for the evaluation of water quality in Czechoslovakian water-supply impoundments. Of 57 such reservoirs, sufficient data were available from 49 for assignment of a saprobity/trophism rank. Four reservoirs were xenosaprobic or ultra-oligotrophic, 18 were oligosaprobic or oligotrophic, 16 were gamma-mesosaprobic or mesotrophic, 7 were beta-mesosaprobic or beta-eutrophic, and 1 was alpha-mesosaprobic or alpha-eutrophic. In addition, 3 impoundments fell between the oligosaprobic/oligotrophic and the gamma-mesosaprobic/mesotrophic categories. The water-quality criteria themselves were also evaluated in this study. Both criteria are quantitative ones and appropriate for such classifications. They are able to distinguish relatively weak differences in time and space for one ecological community as well as differences among various communities within the impoundment. Both are not stable phenomena and their changes indicate fluctuations in the saprobic and trophic conditions, especially along longitudinal and vertical distributions. They react to environmental factors acting within and from outside the body of water. (Sand-PTT)

CLASSIFICATION OF SOME RESERVOIRS IN SR SERBIA (SFR YUGOSLAVIA) BASED ON ANALYSIS OF PLANKTON SPECIES AS INDICATORS OF TROPHIC CONDITIONS.
Institute for Biological Research, Belgrade (Yugoslavia).
V. Martinovic-Vitanovic, and V. Kalafatic.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 831-837, 1990. 1 tab, 18 ref.

Descriptors: *Bioindicators, *Lake classification, *Limnology, *Plankton, *Reservoirs, *Trophic level, *Yugoslavia, Eutrophication, Lentic environment, Nitrates, Nutrients, Phosphates.

During the last few decades, a number of reservoirs have been built in Serbia, creating new aquatic ecosystems with characteristics differing from those of the original river systems. This has resulted in the appearance of biotic assemblages specific to lentic waters, and completely different from those characteristic of flowing rivers. Changes have also occurred in the structure and composition of plankton communities, due to their adaptation to the new environmental conditions. A qualitative and quantitative analysis of plankton was undertaken as an indication of the trophic status of several characteristic reservoirs. Measurements were made of concentrations of phosphates and nitrates--known chemical factors relevant to eutrophication. Based on their morphometric features, nutrient concentrations, and plankton populations, the six reservoirs studied can classified as to trophic type: Bor--oligotrophic; Bovan--oligotrophic-mesotrophic; Zaton--mesotrophic; Gruza--eutrophic; Sava Lake--eutrophic-hypereutrophic; Djerdap--hypereutrophic. It should be emphasized that concentrations of phosphates in the surface waters were generally high. Consequently, these values cannot serve as the only parameter defining organic production of an aquatic ecosystem, and classifying reservoirs solely by determining the concentrations of phosphates may produce erroneous conclusions regarding the trophic status. ECOLOGY OF LOWLAND ZEGRZYNSKI RESERVOIR NEAR WARSAW.
Polish Academy of Sciences, Lomianki. Inst. Ekologii.
Z. Kajak.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 841-850, 1990. 2 fig, 7 tab, 32 ref.

Descriptors: *Limnology, *Phytoplankton, *Reservoirs, *Seston, *Trophic level, *Zegrzynski reservoir, *Zooplankton, Nitrogen, Phosphates, Phosphorus, Poland, Primary productivity, Secchi disks, Secondary productivity, Transparency, Water quality.

The main parameters of the Lake Zegrzynski reservoir are: length 70 km, surface area 33 sq km, average depth 3-4 m, and retention time 5-10 days. Two main inlets provide 58% and 42% of the total inflow, respectively; total P and seston (up to several times). The trophic status of the lake is very high: Secchi disk transparency 0.7-1.3 m, total P 150-300 micrograms/L, phosphate-P 50-170 micrograms/L, total N 2.0-3.0 mg/L. Seston (mg dry weight/L) on the average from 40 in more polluted inlets to 9 at the dam, phytoplankton (mg fresh wight/L) decreases from 30 to 8. Zooplankton biomass is higher (up to 10 mg/L) in standing portions of the reservoir, with rotifers more abundant in the fluvial areas (up to 2 times). Benthos biomass is high, especially in middle lotic areas (up to 1.8 kg/sq m fresh weight), with mollusks being dominant (60-80%). The average biomass (g/sq m) in the middle and lower portions of the lake is 29.0 for phytoplankton, 10.5 for zooplankton, and 1000 for zoobenthos. The estimated annual production (kg/sq m) is 2.9 for phytoplankton, 0.4 for zooplankton, and 1.5 for zoobenthos. The efficiency of plankton plus benthos secondary production expressed as its ratio to seston load and primary production is rather high, 13.7%. (Author's abstract)

INFLUENCE OF IMPOUNDMENTS ON PHYTOSESTON BIOMASS OF TWO SMALL LOWLAND RIVERS-SKIERNIEWKA AND RAWKA IN 1983.
Polish Academy of Sciences, Lomianki. Inst. Ekologii.
A. T. Simm.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 851-860, 1990. 6 fig, 10 ref.

Descriptors: *Biomass, *Dam effects, *Limnology, *Phytoplankton, *Rawka river, *Seston, *Skierniewka River, Algae, Diatoms, Dinoflagellates, Ecosystems, Flagellates, Poland, Population dynamics, Reservoirs, Rivers, Seasonal variation, Species composition, Strowbow Reservoir.

Phytoseston of the Skierniewka River can be defined as a community of planktonic species, typical for polluted rivers in moderate zone. Communities of Pennatae diatoms, typical for clear rivers, occur as the dominant species in the Strowbow Reservoir upstream from the impoundments. In the Rawka River, in spite of the domination by planktonic species, significant participation of Pennatae diatoms can be noticed, from a weak loading of wastewaters. In spring and autumn, centric diatoms (mainly S. hantzschii) dominated in both the Skierniewka and Rawka Rivers. During the summer, the biomass of diatoms decreases, changing into Cylotella spp., Melosira spp., and green algae. In the Skierniewka River the important phytoseston participants were: cryptomonads, euglenoids, and on the lower stretch of the river, blue-green algae. In the Rawka River centric diatoms dominate in the summer. In both rivers, nannoplanktonic species dominated, but their participation decreased in the summer to 60% or less. The most intensive increase of nannoplankton participation was recorded in the largest reservoir in Skierniewice and in the impoundment in Myslakow, situated on the lower stretch of the Skierniewka River where the participation of large flagellates and blue-green algae has been increasing simultaneously with the increase of river pollution. The Strobow (with a 2-7 day retention time) and Skierniewice (8-12 day retention time) Reservoirs had the highest increase in biomass. In the Strowbow Reservoir, a 20-40 times increase of biomass was observed in comparison with a control station situated 250 m downstream. In the Skierniewice Reservoir, the increase was 2-4 times lower, with a maximum of biomass. In reservoirs with retention times not longer than half a day (ie., the Myslakow and Suliszew), the biomass growth was low, and the decrease of phytoseston biomass was noted more often. The lower increase of phytoseston biomass in the impoundment at Skierniewice can be connected with too high a retention time, causing the growth of herbivorous zooplankton, and sedimentation of passively floating diatoms, that could clear up the domination of large flagellates during the summer. IMPORTANCE OF GEOGRAPHICAL ASPECTS IN ENVIRONMENTAL STUDIES OF HYDRO-QUEBEC RESERVOIRS.
Hydro-Quebec, Montreal.
C. Demers.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 913-918, 1990. 1 fig, 1 tab.

Descriptors: *Geography, *Geomorphology, *Hydroelectric power, *Limnology, *Quebec, *Reservoir operation, *Reservoirs, *Surveys, Acid rain, Canada, Erosion, Fertilizers, Floods, Geologic formations, Geologic history, Irrigation, Municipal wastewater, Navigation, Precipitation, Recreation, Social aspects, Stream fisheries, Wastewater disposal.

In addition to the biological and water quality aspects, geographical considerations are important in providing a basis for environmental studies of reservoirs. For the case of Hydro-Quebec reservoirs, knowledge of the specific geographic context allows one to estimate the size and date of the spring flood, using the ratio between rain and snow precipitation, and thus to minimize the risks of flooding. Relationships can be established between sources of acid rain production, prevailing winds and the sites of reservoirs that may be subject to acidification, because of the geology of the subsoil. A definition of the territory in its physiographic regions and smaller sub-regions, as well as knowledge of its recent geological history and past and present geomorphological processes are essential and must be available at the start of a study program. Reservoirs located on a plateau, valley or plain will not have the same surface-to-depth ratio or the same ratio of original area to flooded area. Their shorelines will be differently defined and consist of different materials, and subject to quite different dynamics. Access to tributaries by spawning fish will also be determined by the morphology of the environment. Knowledge of the effects of the last Quaternary glaciation, which resulted in the deposition of erodable clays are important in determining the location of shores sensitive to reservoir erosion. In addition to physical geography, there also aspects associated with human geography which are often overlooked in environmental studies of reservoirs. Aspects of human geography include: native groups performing traditional hunting and fishing activities; recreational activity; industry utilizing water as a production resource; use of irrigation water; release of fertilizers and other chemicals by infiltration; discharge of animal and/or municipal waste; and river navigation. Descriptors: *Limnology, *Phytoplankton, *Population dynamics, *Reservoirs, *Zooplankton, Cluster analysis, Czechoslovakia, Multivariate analysis, Physicochemical properties, Principal component analysis, Seasonal variation, Slapy Reservoir, Species composition.

Data on phytoplankton and zooplankton species composition and abundance as well as physical and chemical conditions from Slapy Reservoir in Czechoslovakia were treated by different methods of multivariate statistics. Three to four consecutive years with rather diversified, extreme hydrological conditions were analyzed. The following methods were used: classification of samples (dissimilarity Euclidian distance; hierarchical clustering: Ward method and average linkage), classification of spe cies and physical-chemical factors (similarity: co relation coefficient; hierarchical clustering: ave age linkage) and ordination (by principal compo nent analysis, correspondence analysis and co strained ordinations: redundancy analysis and c nonical correspondence analysis). The method classification of sequences was used for the fi time for limnological data. Agglomerative classi cation of samples based on standardized data yiel ed five distinct groups: winter samples, late wint to spring samples, mainly summer samples, f summer samples and the winter Closterium aspe Other classifications, although differing, follow t basic seasonal pattern. In the ordination space fined by two principal component axes, three co munity compositional patterns were distinguish for phytoplankton: the September to April patt with low biomass of many species, the May pe characterized by the Cryptomonas aspect and June to August peak with Chlorophyta and bl green algae. The summer peak composition different for the three years observed. In the years with strong stratification blue-green al were highly developed, whereas during the m wet years with reduced stratification a strikin low phytoplankton biomass was observed. Descriptors: *Cycling nutrients, *Kansas, * ing nutrients, *Nitrogen, *Prairies, *St Algae, Nitrates, Phosphates, Riparian vege

A descriptive and experimental approach wa to study patterns of nitrogen concentrati tallgrass prairie streams in Kansas. Nitrate c trations varied depending on the year, seaso of day, stream flow conditions, source of and location where the sample was taken. nitrate concentrations during the dormant decreased from 1982 to 1984, correspond above-normal precipitation during this period. Nitrate concentrations decreased third-order (grass/shrub riparian vegetati fourth-order channels (gallery forests). Nitr ganic N, and total N were higher in a third intermittent stream than in a third-order pe stream. Water from seeps and tributari higher nitrate concentrations than stream however, streams and tributaries had higher ic N than seeps. Maximum nitrate concen during storm flows were directly related magnitude of storms and inversely related frequency of storm events. The activity o trial vegetation influence nitrate concen within streams, seeps, and tributaries; nitr centrations were always higher during pe vegetation dormancy. Aquatic biota inf both spatial patterns (downstream decrea

rate concentrations and increase in organic N) and iel patterns of nitrate concentration (night > ay). Uptake rates of nitrate by biota were greater uring the day than during the night as determined y experimental addition of nitrate. Nitrogen and/ r phosphorus limitations of algal growth were sted experimentally using nutrient-diffusing sub- rata (clay saucers filled with enriched agar) and richment of artificial channels. Addition of N d P in combination increased algal biomass hlorophyll a and ash-free dry mass) over control single addition of N or P. Thus, algal biomass as N and P limited; however, individual taxa sponded to specific N and/or P concentrations atomic N:P ratio. (Author's abstract)

SEASONAL DELIVERY OF THE PARTICULATE FORMS OF PHOSPHORUS TO LAKE GENEVA FROM THE UPPER RHONE RIVER.
Geneva Univ. (Switzerland). Inst. F.-A. Forel.
D. Burrus, R. L. Thomas, J. Dominik, and J. P. Vernet.
Aquatic Sciences AQSCEA, Vol. 52, No. 3, p 221-235, 1990. 5 fig, 3 tab, 15 ref.

Descriptors: *Eutrophication, *Lake Geneva, *Nutrients, *Path of pollutants, *Phosphorus, *Rhone River, *River sediments, *Seasonal variation, *Switzerland, *Water pollution sources, Pollution load, River flow, Sediment discharge, Turbidity.

Large volume water samples were taken at the mouth of the Upper Rhone River as it enters Lake Geneva (Switzerland). Samples were taken every two weeks from January 1982 until August 1983. Water samples were analyzed for total phosphorus, and soluble reactive phosphorus and were centrifuged in the field using a continuous flow centrifuge to recover the suspended solids following sieving at 63 micrometers. The <63 micrometers solids were analyzed for total particulate phosphorus, organic phosphorus, apatite phosphorus and non-apatite inorganic phosphorus. The >63 micrometer particles were similarly analyzed and the weight of total solids in both size fractions recorded. Results were compared throughout the period of record to the hydrograph situated at Porte de Scex. The annual cycle of the Rhone can be divided into a low turbidity, low flow winter period and high flow, high turbidity summer season. Turbidity was well related to discharge. The >63 micrometer sediment was mobilized at 200 cu m/second and thereafter increased in concert with, though at a faster rate than, the <63 micrometer fraction. The coarse fraction contained significant quantities of phosphorus and in 1982 accounted for 26% of the total particulate phosphorus loading. Organic phosphorus and non-apatite inorganic phosphorus were higher in the winter period than in the summer season though apatite phosphorus remained constant throughout the year. Organic phosphorus was believed to be driven primarily from point sources whercas non-apatite inorganic phosphorus, in addition to point sources, had secondary sources in spring and summer due to sheet erosion from the agricultural soils of the valley. Loadings of phosphorus were calculated by four methods which showed internal consistency though they were higher than previous estimates. Bioavailable phosphorus was estimated to account for some 20% of the total phosphorus loading of some 1500 tons, bioavailable phosphorus was taken to be the sum of soluble reactive phosphorus and non-apatitie inorganic phosphorus and was that portion of the phosphorus load believed to be available to generate phytoplankton growth. VERTICAL MIXING IN UBERLINGER SEE, WESTERN PART OF LAKE CONSTANCE.
Heidelberg Univ. (Germany, F.R.). Inst. fuer Umweltphysik.
G. Heinz, J. Ilmberger, and M. Schimmele.
Aquatic Sciences AQSCEA, Vol. 52, No. 3, p 256-268, 1990. 6 fig, 3 tab, 25 ref.

Descriptors: *Eddy diffusion, *Germany, *Lake Constance, *Lake morphometry, *Limnology, *Water circulation, *Water temperature, Diffusion coefficient, Fluctuations, Lake circulation, Lakes, Phosphorus, Seasonal variation.

Depth variable vertical eddy diffusion coefficients for heat were calculated from continuously measured temperature profiles in Uberlinger See (western part of Lake Constance, Germany). The temperatures were averaged over vertical intervals of 10 m yielding 14 discrete values (maximum depth of Uberlinger See: 147 m). A linear fit from June 10 to September 29, 1987 was used to smooth the significant temperature fluctuations caused by internal seiches of Lake Constance. Assuming horizontal homogeneity for the smoother data, the Gradient-Flux-Method was applied to compute vertical diffusion coefficients for heat at different depths using the depth variable volumes and surfaces of the 14 layers. The resulting mean diffusion coefficients for the period from June to September were 0.04 sq cm/sec near the thermocline and up to 0.8 sq cm/sec in deeper strata (accuracy: +/- 50%). It was shown that horizontal mixing between Uberlinger See and Obersee (main lake) altered the computation of vertical diffusion coefficient by less than 50%. A relationship between vertical diffusion coefficients and stability frequency was found that corresponded well to the theory of internal wave induced turbulence. Combining the diffusion coefficients with measured phosphorus profiles, a phosphorus flux from the hypolimnion to the epilimnion of mg P/sq m/day was calculated, corresponding to about 20% of the average external loading per area of Lake Constance in 1986. (Author's abstract)

PLANKTONEUSTONIC ALGAE IN THE SURFACE FILMS OF LAKE ZURICH: OCCURRENCE AND DEPENDENCE ON PHYTOPLANKTON SUCCESSION.
Zurich Univ., Kilchberg (Swizerland). Hydrobiological-Limnological Station.
A. Nageli, and F. Schanz.
Aquatic Sciences AQSCEA, Vol. 52, No. 3, p 269-286, 1990. 6 fig, 1 tab, 48 ref.

Descriptors: *Lake Zurich, *Limnology, *Phytoplankton, *Succession, *Switzerland, *Taxonomy, Algae, Aquatic populations, Lakes, Neuston, Population density, Species composition.

Samples of surface films and of the underlying bulk water at 0.2 m depth were taken in Lake Zurich (Switzerland) on 48 occasions in 1986, 1988 and 1989, with the aim of assessing the appropriateness of applying existing neuston nomenclature to the organisms found in these films, of determining which organisms accumulate there during which periods of time, and of assessing the importance of the phytoplankton community in the development of neustonic biocoenoses. Lake Zurich surface films were found to support a community of high population density, consisting of organisms which had migrated from the benthal or pelagial, or which had entered the film via the atmosphere or inflowing rivers. In all samples, species originating from within the phytoplankton community accounted for the greatest proportion of the total abundance. Several of these species were found to exhibit a special preference for the surface biotope, for example, those with a relative frequency exceeding 10%, a mean enrichment factor exceeding 100, and in the majority of cases, with a greater concentration of individuals in the surface film than in the underlying bulk water layer. Those organisms occurring in the surface films of large water bodies exhibiting these criteria should be considered planktoneustron, whereas the occurrence of other species in surface films should be considered merely coincidental. The fact that planktoneustonic algae are dominant in the surface films of Lake Zurich means that changes in the species composition of the planktonic algal biocoenosis directly affect the species composition of the neustonic algal biocoenosis. Thus, just as in the underlying bulk water, a succession can be observed in the algal biocoenosis of the surface films. However, because of the higher abundance of

planktoneustonic algae there, this succession is distinct from that occurring in the pelagial. Factors bringing about these differences which are appropriate for dominant planktoneustonic algae are: alterations in specific gravity; positive phototaxis; and enhancement of growth rates in surface films as compared with the underlying bulk water. EXPERIMENTAL COMPARISON OF THE EFFECTS OF BENTHIVOROUS FISH AND PLANKTIVOROUS FISH ON PLANKTON COMMUNITY STRUCTURE.
Oklahoma Univ., Norman. Dept. of Zoology.
J. Qin, and S. T. Threlkeld.
Archiv fuer Hydrobiologie AHYBA4, Vol. 119, No. 2, p 121-141, 1990. 6 fig, 5 tab, 26 ref. NSF grant DEB 8506112.

Descriptors: *Experimental design, *Fish behavior, *Fish diets, *Fish populations, *Lake fisheries, *Limnology, Algal growth, Benthos, Carp, Ecological effects, Fish, Lake sediments, Lakes, Oklahoma, Phytoplankton, Plankton, Population dynamics, Silverside.

Three experiments of factorial design were conducted to evaluate how benthivorous fish, carp (Cyprinus carpio) and planktivorous fish, silverside (Menidia beryllina) alter plankton community structure. Experiment 1 involved two benthivorous fish treatments (Cyprinus and no fish), three treatments affecting resuspension of sediments (mixing by paddle, use of screens to limit fish access to sediments, and no mixing), and two sediment treatments (present and absent) in water from two lakes (Lakes Broken Bow and Texoma, Oklahoma) in a cross-classified experimental design. Experiment 2 included either addition or no addition of planktivorous fish (Menidia), nitrogen or phosphorus in a cross-classified design. Experiment 3 examined the combined effects of planktivorous fish and benthivorous fish on plankton. Treatments included presence or absence of Cyprinus, Menidia and sediment and nutrient treatments using presence or absence of dead fish, in a cross-classified experimental design. In Experiments 1 and 3, benthivorous fish enhanced algal fluorescence, seston particles and algal filament abundance. The enhancement of phytoplankton by benthivorous fish occurred whether or not sediment was present and, when sediment was present, whether or not fish had access to the sediment. These results suggest that benthivorous fish do not affect phytoplankton solely by releasing sediment-bound nutrients. Planktivorous fish enhanced phytoplankton and suppressed large herbivorous zooplankton in experiment 2, but in experiment 3, planktivorous fish did not enhance phytoplankton although crustacean zooplankton were suppressed. The lack of effect of planktivorous fish on phytoplankton was not altered by the addition of nutrients. In experiment 3, neither benthivorous nor zooplanktivorous fish affected how the other fish affected phytoplankton when they were stocked alone. (Mertz-PTT)

FOODWEB RESPONSE TO THE EXPERIMENTAL MANIPULATION OF A BENTHIVORE (CYPRINUS CARPIO), ZOOPLANKTIVORE (MENIDIA BERYLLINA) AND BENTHIC INSECTS.
Oklahoma Univ., Kingston. Biological Station.
W. B. Richardson, S. A. Wickham, and S. T. Threlkeld.
Archiv fuer Hydrobiologie AHYBA4, Vol. 119, No. 2, p 143-165, 1990. 5 fig, 3 tab, 83 ref. NSF grant BSR 8805681 and DOE contract DE-AC-09-76SR00819.

Descriptors: *Algal growth, *Aquatic insects, *Benthos, *Carp, *Food chains, *Limnology, *Population dynamics, *Zooplankton, Aquatic production, Benthic fauna, Biomass, Ecological effects, Fish behavior, Fish diets, Protozoa, Rotifers, Secondary productivity.

Key components of benthic and water column foodwebs were manipulated in 18 large outdoor tanks to test the hypothesis that these foodwebs are strongly coupled. Using a replicated, cross-classified design the presence and absence of (1) a benthivore (common carp: Cyprinus carpio), (2) particulate feeding zooplanktivore silversideL: (Menidia beryllina), and (3) insect benthos were controlled. Fish were the primary determinants of foodweb structure. Both fish strongly enhanced algal biomass (in situ algal fluorescence), but only Cyprinus enhanced algal production. Both fish suppressed large zooplankton, while Menidia also suppressed small individuals. Rotifers and protozoa were enhanced in the presence of both fish. This suggests phytoplankton were responding primarily to fish biomass, not suppression of algal grazers. Cyprinus enhanced bacterial secondary production, while bacterial biomass was enhanced by Cyprinus only in the presence of Menidia. Only Cyprinus significantly suppressed densities of benthic invertebrates. Benthic insects had few direct effects on the water column foodweb. Large numbers of significant 2-way interactions suggest that treatment effects were rarely additive. This result precluded predictions of the effects of combinations of the two fish species based on single species experiments. There was little indication of strong coupling between benthic and water column foodwebs. Only through the feeding activity of Cyprinus were benthic resources translated into water column biomass. FIELD STUDY OF THE EFFECTS OF WATER TEMPERATURE, DISCHARGE AND TROUT ODOUR ON THE DRIFT OF STREAM INVERTEBRATES.
Toronto Univ. (Ontario). Div. of Life Sciences.
D. D. Williams.
Archiv fuer Hydrobiologie AHYBA4, Vol. 119, No. 2, p 167-181, 1990. 2 fig, 5 tab, 33 ref.

Descriptors: *Fish behavior, *Invertebrates, *Stream biota, *Stream discharge, *Temperature effects, *Water temperature, Amphipods, Beetles, Caddisflies, Chironomids, Copepods, Dipterans, Ecological effects, Fish, Mayflies, Oligochaetes, Ostracods, Stoneflies, Streams.

A manipulative field study was conducted on a uniform riffle on the east branch of Duffin Creek, Durham County, Ontario, Canada, in September, 1981 to examine the effects of three important environmental factors on a variety of drifting invertebrate taxa. Factors chosen included water temperature, discharge, and presence of predatory fishes. Day/night differences and catch-net variation were also examined. Drift response varied according to the scale of changes in water temperature and discharge and also among taxa in the hardwater stream. During the period of wide-ranging discharge and water temperature, overall night-time drift density was positively related to both discharge and minimum temperature, whereas during more constant conditions it was related to discharge alone. Analysis of catches of individual replicated drift nets showed considerable variance. No taxon showed a significant relationship with temperature or discharge during the day but some did at night. Chironomids and mayflies were associated with minimum night-time temperature only, while caddisflies, beetles and ostracods were associated with discharge; stoneflies and mites were associated with both factors; amphipods, oligochaetes, copepods and non-chironomid dipterans were not associated with either factor. During the day, the overall density of drifting animals was greater in the presence of trout odor although density of some taxa was the same in both fish and fishless sections of the stream. At night, only three taxa drifted significantly more in the presence of trout. Mayflies, stoneflies and caddisflies drifting at night were larger in the presence of trout but amphipods were smaller. The Philippine Archipelago, which compr more than 7100 islands, has an approximate are 1,083,000 ha of wetlands. Although the wetl types have been classified as mangroves, swam estuaries and deltas, freshwater marsh, aquacult ponds, rivers, lakes, and man-made resevoirs, coastal region is predominantly a mangrove system. In 1918, the mangrove forest was appr mately 400,000 ha; by 1978, the area was redu to 146,140 ha, with only 100,564 ha remainin 1987. This rapid loss has been caused mainly timber extraction and aquaculture developm Currently, about 95% of the aquaculture indus supporting about 2,000,000 people, is done ponds which were once mangroves, causing loss of another 3500 ha every year. In an atte to rectify this alarming situation, both governm and private agencies have conducted extensiv ventories to determine the exact area of remai mangroves. The rehabilitation of those areas w were destroyed as a result of repeated overuse previous mismanagement is the specific focu future government policies. (D'Agostino-PTT) W91-02473

MANGROVE FOREST RESOURCES IN IN NESIA.

Descriptors: *Ecological effects, *Forest ma ment, *Forestry, *Indonesia, *Mangrove sw *Wetland forests, *Wetlands, Agriculture, culture, Regulations, Resources managemen viculture.

Mangroves are highly specialized and co ecosystems which form a transitional link be terrestrial and aquatic biota. In Indonesia, groves occupy approximately 4.25 million h resenting almost 20% of the world's mar

forests. Of this, 2.94 million ha are stretched along the coast line of Irian Jaya and are still relatively virgin and unexploited. However, the remaining 1.31 million ha are located in the more populated areas, such as Java, Sumatra, and Kalimantan, where these habitats have been extensively exploited. The primary human disturbances include residential settlement, agricultural land use, aquaculture development, and the for-profit activities of forestry and fisheries. Limiting the exploitation of the mangroves based on conservation principles has been attempted. Some forest companies have used a management scheme which divides the mangrove forest into sub-blocks of 120 ha, and permits only 4 ha/yr to be cut from each sub-block to insure a 30-year rotation. The government, through the Ministry of Fisheries and the Ministry of Forestry, has adopted a general policy for the protection, conservation, and wise use of the mangrove resources. It imposes limitations on cutting and preservation of mangrove forests. A 'green belt' 100-400 m wide must be retained along the coast in order to preserve the ecosystem and to insure natural regeneration. A number of mangrove reserves in coastal areas and natural conservation areas have been established. Other government agencies and research institutions are studying the ecosystem in an effort to preserve the mangroves for perpetual human use. (D'Agostino-PTT)

MANGROVES IN KAMPUCHEA.
Humboldt State Univ., Arcata, CA. Dept. of Forest Economics.
M. S. Sin.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 59-62, June 1990. 4 ref.

Descriptors: *Forest management, *Forestry, *Kampuchea, *Land use, *Mangrove swamps, *Wetland forests, Agriculture, Aquaculture, Resource management, Water resources management.

The total area of mangroves in Kampuchea is estimated at 37,000 ha. However, the forest area of primary importance is located north of Koh Kong within a rectangular area of only 8 x 20 km. This is a multi-use resource, consisting mainly of Rhizophora conjugata, R. mucronata, Avecennia, Bruguiera, and Ceriops. Large quantities of mangrove are used in the production of firewood and charcoal, tannin, and nipa for domestic use. Little is known about how much the mangrove forest affects the production of fish. However, the practice of active aquaculture is insignificant at present. In some areas where mangrove forests have been reclaimed for agricultural use, coconut, pineapple, rice, and black pepper have been planted. Although there is no apparent population pressure on the mangrove forest, some areas have already been reduced to low shrubs of no value. It is suggested that future development of well-formulated management plans will ensure both optimal use of land already cleared, as well as reforestation of areas where declines have occurred. INVENTORY AND MONITORING OF FORESTED-WETLAND RESOURCES OF ASEAN.
Pertanian Malaysia Univ., Serdang. Faculty of Forestry.
A. Jusoff, and N. M. Majid.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 63-79, June 1990. 2 fig. 2 tab. 24 ref.

Descriptors: *Forest management, *Land management, *Network design, *Resources management, Surveys, *Wetland forests, *Wetlands, Brunei, Data acquisition, Ecological effects, Estuaries, Forest ecosystems, Indonesia, Malaysia, Monitoring, Philippines, Singapore, Thailand, Water quality, Water resources management, Wetland restoration.

Forested wetlands are highly productive ecosystems which not only provide valuable forest products, but also contribute to estuarine water quality, and play a crucial role in the life-cycles of commercially important aquatic species. In this regard, there is an urgent need for the proper classification, management, and utilization of these lands to maximize their productivity in response to the growing demands of the increasing population in the ASEAN region (Brunei, Indonesia, Malaysia, The Philippines, Singapore, and Thailand). The authors suggest that an initial step toward this goal is an extensive inventory of the forested-wetland resources, organized and reported from a regional perspective. Furthermore, the causes of degradation of forested areas should also be identified and monitored. It is also proposed that a network should be established to create and maintain a multi-level information structure for the monitoring of ASEAN forested-wetland resources for information exchange and future planning. Careful inventory and monitoring of these resources will, it is hoped, provide reliable and relevant information for a future long-term management of the wetland forests in the ASEAN region. STATUS AND DISTRIBUTION OF FORESTED WETLANDS IN TROPICAL SOUTH AMERICA.
Max-Planck-Inst. fuer Limnologie zu Ploen (Germany, F.R.).
H. Klinge, W. J. Junk, and C. J. Revilla.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 81-101, June 1990. 1 fig, 5 tab, 130 ref.

Descriptors: *Ecological effects, *Forest ecosystems, *Forest management, *Forest watersheds, *Land use, *Soil-water-plant relationships, *South America, *Wetland forests, *Wetlands, Brazil, Forestry, Agriculture, Guyana, Hydroelectric plants, Paraguay, Reforestation, Tropical regions, Wetland restoration.

Physiographically, tropical South America is characterized primarily by large watersheds (Amazon, Orinoco, Magdalena, Parana-Paraguay, Sao Francisco), a very long coastland, and uplands (Andean Cordillera, the highlands of Guayana, and central Brazil). Poor drainage, sheet-flooding, fluctuating water levels, and flood pulses contribute to the maintenance of wetlands, mostly forested, which cover approximately 20% of this region's total area. This literature review data discusses which classifies these tropical forests into four types: tidal, seasonal, aseasonal, and permanent. Their geographical delineation, extent, floristics, and structure are also documented. As observed in other wetland areas, agriculture, animal husbandry, and timber production, as well as hydroelectric power projects, exploit these sites and are the main causes of their destruction. It is concluded that future studies addressing mapping, ecological interplay, seedling establishment, and forest regeneration should be carried out to obtain a more complete knowledge of the composition of these wetlands. VENEZUELAN FLOODPLAIN STUDY ON THE ORINOCO RIVER.
Fundacion La Salle de Ciencias Naturales, San Felix (Venezuela). Estacion Hidrobiologica de Guayana.
G. Colonnello.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 103-124, June 1990. 12 fig, 2 tab, 25 ref. CONICIT (The National Council of Scientific and Technological Investigations) Grant S1-1920.

Descriptors: *Flood plain forests, *Flood plains, *Forest ecosystems, *Orinoco River, *Soil-water-plant relationships, *Venezuela, *Wetland forests, Ecology, Ecosystems, Geomorphology, Species diversity, Topography, Vegetation.

To date, most studies concerning floodplain ecology have been conducted in the Amazon basin. Information about the Orinoco flood plain in Venezuela is currently lacking. With the use of transact surveys, aerial photographs, and horizontal profile elaboration, the floodplain origins, principal geomorphological formations and floristic composition of Laguna de Mamo in eastern Venezuela can be described. The forest has been physiognomically characterized by three strata: species typical of the lower stratum (Simira rubescens and Caesaria), of the intermediate stratum (Symmeria paniculata and Pterocarpus), and of the upper strata (Piranhea trifoliata and Lonchocarpus). Ten species of climbing vines and 34 tree species have been recorded on a 0.2-ha sample plot. The observed difference in floristic diversity between the depression areas and levees was attributed to differences in inundation and soil types. Together, the topographical and geomorphological make-up of this area will continue to maintain the present physico-biotic characteristics of the existing floodplain complex. (D'Agostino-PTT)

Descriptors: *Amazon River Basin, *Forest ecosystems, *Soil-water-plant relationships, *Species diversity, *Wetland forests, *Wetlands, Ecosystems, Flood plains, Flooding, Surveys, Tectonics, Vegetation.

Western Amazonia is a mosaic of fossil and current floodplains produced by vast lateral river migrations. Forest ecosystems of the Amazon basin are known to reach very high diversity. Floristic inventories show that species richness is clearly higher in upland than in wetland forests. The analysis of differential faulting and folding tectonic effects on the two western Amazonian morphostructural units clearly indicates that area affected by fluvial dynamics are rather limited within well-defined depressions, the tendency of which is subsidence or entrenchment. Most upland forests have not been affected by fluvial dynamics since the Pleistocene: plant species diversity is highest in these 'terra firme' forests which cover vast areas. While it is argued that the reduced diversity in the wetlands could be due to flooding consequences, it is mainly concluded that the richness of species in the upland forests is the result of their constant favorable ecological conditions. Descriptors: *Flooding, *Forest ecosystems, *Land use, *Resources management, *Ucayali River, *Vegetation, *Wetland forests, *Wetlands, Agriculture, Forest management, Forestry, Land management, Peru.

In Peruvian Amazonia, eleven types of vegetation have been determined in a 2200 square km area of the lower Ucayali River. Of these, ten are forests and one is a floating meadow. Forest ecosystems cover 2133 square km (97%), of which 1335 square km (61%) are wetlands with six forest types, two under the influence of local rainfall and the other four related to the river's flooding pattern. Furthermore, a consistent correlation was observed between flooding patterns, physiographic characteristics and types of vegetation. Although most of the economic activities of the area's fifteen villages are carried out in forested wetlands, little attention has focused on their structure, composition, or fluvial dynamic patterns. Consequently, no regula-

tions which address optimal multi-land use practices, including agriculture, cattle-raising, wood extraction, agroforestry, fishing, and hunting, have been developed. It is concluded that future studies involving floristics, regeneration, reproductive biology, and water dynamics are necessary to construct a sound management policy for these wetland resources. PALM COMMUNITIES IN WETLAND FOREST ECOSYSTEMS OF PERUVIAN AMAZONIA.
Institut Francais de Recherche Scientifique pour le Developpement en Cooperation, Lima (Peru). Mission ORSTOM au Perou.
F. Kahn, and K. Mejia.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 169-179, June 1990. 6 tab, 21 ref.

Descriptors: *Flooding, *Forest ecosystems, *Palm trees, *Peru, *Soil-water-plant relationships, *Wetland forests, *Wetlands, Distribution patterns, Ecosystems, Huallaya River Basin, Population density, Species diversity, Ucayali River Basin.

Palms are found in all wetland forests throughout the Amazon basin, with their species distribution being clearly related to flooding patterns and water properties. In this study, surveys of palm communities were carried out in the lower Ucayali and upper Huallaya River valleys, located in the lowland and Andean piedmont regions of Peruvian Amazonia. These ecosystems were characterized by species association, density, and vertical distribution of their palm communities. Palms may form almost monospecific stands (e.g. Mauritia flexuosa swamps) or multispecific communities (e.g. seasonal swamp forests in the upland valleys or the periodically flooded alluvial soils). In forests flooded by blackwater streams, palm diversity is low. However, palm density is often high with a characterstic patchy distribution pattern due to clustered species. Together these data delineate the distinct characteristics of each palm community, information which is potentially useful for a more complete definition and identification of the wetland forests in Peruvian Amazonia. Forested wetlands are an invaluable ecological resource which provide wildlife habitats, outdoor recreation, and forestry products, and affect both flood control and water quality. Despite such benefits, wetland areas in the United States have decreased dramatically, with some striking regional losses as high as 40-80%. To a large extent, this is the result of past policies, mainly at the federal level, based on economic decisions which favored wetlands development. Historically, however, both public and private agencies have differed in their assessment of the cost to benefit ratio regarding the preservation of such lands versus converting them to other uses. Projected trends, such as decreased availability of wetland areas suitable for agriculture, current protective federal policies, changes in the legal system, and improved evaluation techniques, will ensure more intelligent management decisions and reduced wetland losses in the future. Descriptors: *Arizona, *Distribution patterns, *Flood plains, *Forests, *Geomorphology, *New Mexico, *Riparian vegetation, *Species composition, *Wetland forests, Statistical analysis, Streamflow, Trees.

Although fluvial geomorphic processes determine the characteristics of a stream channel and its adjacent floodplain terraces, their relationships to riparian vegetation patterns are not completely understood. The effects of elevation, stream direction, stream gradient, and valley cross-sectional area on the distribution of riparian tree species and community types were examined at 153 sites in Arizona and New Mexico. Canonical discriminant analysis of physical site characteristics both within and among the 28 classified communities demonstrated that elevation was the most significant factor for all community types, all riparian forest community types, and all riparian scrub community types. Both stream gradient and stream direction also correlated significantly, but on a more limited and local level. Valley cross-sectional area had the least association with riparian vegetation of the four variables examined. Tree distribution studies showed that for some species, dominance or codominance was also directly related to site characteristics such as elevation and direction of stream flow. On west-flowing streams, for example, Arizona walnut (Juglans major) was codominant with Arizona sycamore (Platanus wrightii), while on east-flowing streams, sycamore was absent while the walnut species dominated the stands. The conclusion that distinctive geomorphic settings and riparian plant communities characteristically coexist along an elevational gradient agrees with similar findings in eastern Nevada. The classification of plant communities is a particularly useful tool for the comparison of similar ecological areas in the development of land management plans. Although numerous protocols are currently available, it is of prime importance to determine the minimal number of observations necessary to adaquately delineate an individual plant population. In addition, riparian communities in the southwestern United States often occur in patches and isolated pockets along stream corridors, making classifications of community types highly dependent on sampling design and methodology. In this study, the relationship between sampling intensity and species richness was investigated at five sites in south-central Arizona, with dif
fering species richness. The findings consistentl
showed that species ranks, tree density, and basa
area estimates required a minimum of 10 observa
tions to stabilize the standard error. Using boot
strap subsampling techniques, it was determine
that the variability in species density ranks for th
most frequent species, stabilized with approximate
ly 10-20 plots. As species richness increased, so di
the variability associated with estimating rank
Studies based on only a few specifically selecte
sample plots may not produce reliable and repea
able results. (D'Agostino-PTT)

Descriptors: *Alaska, *Copper River, *Deltas, *Earthquake flood, *Forest ecosystems, *Plant populations, *Tidal floods, *Wetland forests, *Wetlands, Coastal environment, Earthquakes, Estuaries, Levees, Salinity, Suspended sediments, Tectonics, Vegetation.

The delta formed by the Copper River stretches for more than 75 km along the south central coastline of the Gulf of Alaska. All major rivers that flow into the delta carry extremely high levels of suspended sediments. Due to an earthquake in 1964, subtidal and intertidal areas became interchanged, and marshland advanced into the intertidal zone. Concurrently, vegetation on many new levees began to change from herbland to shrubland, most probably due to changes in tidal inundation and water salinity. Since the estuarine circulation is dominated by freshwater, higher tides merely raised the level of freshwater on the wetlands. The initial post-earthquake invasion of woody plants was confined to natural levees. However, recently the shrubs have moved seaweed into new inter-tidal marshland. Furthermore, shrubland, woodland, and forest vegetation analogous to that developing on some supertidal levees is now present on older wetland habitats further inland. Although the uplift has altered locations and growth rates of the various plant species, the characterisitic nature of wetland plant succession has not been changed. (D'Agostino-PTT)

LONG-TERM TRENDS IN THE BALD-CYPRESS (TAXODIUM DISTICHUM) RESOURCE IN LOUISIANA (U.S.A).
Louisiana State Univ., Baton Rouge. Center for Wetland Resources.
V. H. Conner, and J. R. Toliver.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 543-557, June 1990. 4 fig, 2 tab, 74 ref. Louisiana Sea Grant Program and McIntire-Stennis Project LABO1591.

Descriptors: *Baldcypress trees, *Ecological effects, *Forest ecosystems, *Forestry, *Louisiana, Swamps, *Wetland forests, *Wetlands, Hydrology, Long-term planning, Nutria, Plant populations, Reforestation.

The baldcypress has long been a dominant timber species in Louisiana's wetland forests. Early settlers recognized the value of this species, and due to its durability and workability it remained a valuable commodity of the lumber industry from the 18th through the early 20th centuries. Early estimates of the area of baldcypress forests range from 0.67 to 3.64 million ha. Baldcypress timber was cut extensively from 1890 to 1925 when the last virgin stands of timber in the state were depleted. In 1934, there were 0.66 million ha of cutover baldcypress forests in Louisiana. However, recent estimates indicate that there are only 0.14 million ha of baldcypress swamp forest remaining in the state. Regeneration problems have increased in recent years due to human changes in hydrology and natural subsidence, and the introduction of the rodent, nutria, from South America. Furthermore, even though the growing stock in the state continues to increase, larger trees are being harvested and regeneration is insufficient to restock these stands, resulting in declining total acreage. Methods to plant and protect seedlings and to stem alteration of the area's natural hydrologic processes must be developed to ensure the survival of these wetland forests for the future. CLASSIFICATION OF MANGROVE FOREST BY USING 1:40,000-SCALE AERIAL PHOTOGRAPHS.
Pertanian Malaysia Univ., Serdang. Faculty of Forestry.
S. Ibrahim, and I. Hashim.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 583-592, June 1990. 7 tab, 12 ref.

Descriptors: *Aerial photography, *Classification, *Mangrove swamps, *Mapping, *Species composition, *Surveys, *Wetland forests, *Wetlands, Data acquisition, Forests, Remote sensing, Vegetation, Watershed management.

The species groups of mangrove forest can be delineated, classified, and mapped by using 1:40,000-scale aerial photographs. A peninsular Malayan mangrove forest (from Kemaman to Kuantan) was delineated in two phases: interpretation of black-and-white panchromatic photographs, and field survey. The results indicate that there are three mangrove forest types, namely the Rhizophora, the Avicennia-Sonneratia, and the mixed-mangrove type which can be delineated with 90% correct interpretation. In an area of 2214 ha, of which 2% is Avicennia-Sonneratia, 24% Rhizophora and 74% mixed-mangrove, Avicennia-Sonneratia has the highest stand density with 13,348 trees ha -1, followed by Rhizophora with 6697 and mixed-mangrove forest with 1997. It is concluded that aerial photography is a useful method for the delineation, classification, and mapping of mangrove forests. (D'Agostino-PTT)

USE OF HIGH-ALTITUDE AERIAL PHOTOGRAPHY FOR INVENTORYING FORESTED WETLANDS IN THE UNITED STATES.
Fish and Wildlife Service, Newton Corner, MA.
R. W. Tiner.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 593-604, June 1990. 2 tab, 10 ref.

Descriptors: *Aerial photography, *Mapping, *Wetland forests, *Wetlands, Classification, Data interpretation, Forests, Infrared imagery, Maps, National wetlands, Surveys, Watershed management.

Currently, the National Wetlands Inventory Project (NWI) prepares wetland maps using stereoscopic interpretation of high-altitude aerial photographs. This is a multi-step procedure which includes preliminary aerial photography, selection of specific field study sites, stereoscopic interpretation of aerial photos, preparation of large-scale wetland maps, coordination of preliminary map review, and subsequent editing for final map production. Leaf-off, color infrared aerial photography from the early spring is the method of choice for detecting deciduous forested wetlands in temperate regions. Wetlands which are difficult to identify on the ground, such as evergreen forested wetlands, flooded deciduous forests, rain forest regions and hydrologically altered forests are the most difficult to photo-interpret. In these cases topographic landscape position studies, subtle photo signatures, more extensive field-work, and collateral information, such as soil surveys, must be included to produce useable maps. It is concluded that high-altitude aerial photography is an efficient and cost-effective means of identifying and classifying wetlands for inventory preparation on a national, regional, and statewide basis. SYNOPTIC INVENTORY OF RIPARIAN ECOSYSTEMS: THE UTILITY OF LANDSAT THEMATIC MAPPER DATA.
Environmental Monitoring Systems Lab., Las Vegas, NV.
M. J. Hewitt.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 605-620, June 1990. 8 fig, 6 tab, 17 ref.

Descriptors: *Data acquisition, *Mapping, *Riparian vegetation, Ecosystems, Washington, Yakima River.

It has been estimated that almost 66% of the naturally occurring riparian vegetation in the United States has been eradicated since 1776. In spite of the critical importance of riparian zones to the maintenance of wildlife populations, no adequate methods currently exist for the synoptic inventory and assessment of this critical resource. This study analyzes the feasibility of utilizing Landsat Thematic Mapper data for the inventory of riparian habitats along the Yakima River of central Washington. Although final map accuracy assessment was determined to be only 80%, it was concluded that an adjustment of the experimental design could significantly increase map accuracy. The recommended parameters include the employment of both a temporal approach, such as selecting images from different seasons, as well as a buffer algorithm that masks out all pixels greater than n distance from the water class. With these modifications, high-resolution satellite systems are potentially useful in providing synoptic inventory maps of riparian habitats. (D'Agostino-PTT)

ECOLOGY OF WATER-FILLED TREEHOLES IN AUSTRALIAN RAINFORESTS: FOOD WEB REASSEMBLY AS A MEASURE OF COMMUNITY RECOVERY AFTER DISTURBANCE.
University of New England, Armidale (Australia). Dept. of Ecosystem Management.
B. Jenkins, and R. L. Kitching.
Australian Journal of Ecology AJECDQ, Vol. 15, No. 2, p 199-205, June 1990. 5 fig, 29 ref.

Descriptors: *Ecology, *Ecosystems, *Food chains, *Rain forests, *Treeholes, Australia, Phytotelemata, Predation, Species composition, Species diversity, Subtropic zone.

Ten water-filled tree holes which belong to the groups of lentic, aquatic ecosystems known as phytotelmata, in a subtropical rainforest were emptied out thereby posing a major perturbation on the community of organisms which occupied these habitat units. During the process of food web reassembly following this disturbance, the average number of predator species in the web increased as did the average number of prey species. Predator-

prey ratios increased in magnitude with the number of days after the disturbance. Furthermore, the characteristic mean predator-prey ratio of the original community was gradually restored as the food web reassembled. The number of prey species was found to be a better predictor of the number of predator species during community recovery than vice versa. The increasing number of trophic links in the food web over the period of reassembly, due mainly to the increase in the number of predacious species in the web, provided a good overall measure of community recovery. A model of food web reassembly using the relationships among food web statistics can be used to assess the rate of recovery of a community after a disturbance of the food web at the regional level of resolution. Food web statistics may also be useful in developing models for large ecosystems. (Author's abstract)

VEGETATION CHANGE ON THE OUSE WASHES WETLAND, ENGLAND, 1972-1988 AND EFFECTS ON THEIR CONSERVATION IMPORTANCE.
Royal Society for the Protection of Birds, Sandy (England).
N. D. Burgess, C. E. Evans, and G. J. Thomas.
Biological Conservation BICOBK, Vol. 53, No. 3, p 173-189, 1990. 5 fig, 4 tab, 22 ref.

Descriptors: *Conservation, *Ecology, *Ecosystems, *Grasses, *Grasslands, *Vegetation, *Wetlands, England, Flooding, Grazing, Hay, Ouse Washes, Resources management, Species composition, Species diversity, Vegetation effects.

A re-survey of wetland vegetation on the Ouse Washes in 1988 indicated that it has changed dramatically in 16 years. Glyceria maxima swamp (National Vegetation Classification (NVC) S5) and Agrostis stolonifera-Alopecurus geniculatus inundation grassland (NVC S13) have more than doubled their area, whereas Phalaris arundinacea swamp (NVC S28), Holcus lanatus-Deschampsia cepitosa coarse grassland (NVC MG9) and Carex riparia swamp (NVC S6) have declined by at least three-quarters of their previous area. Increased flooding, especially in the late spring and early summer, and reduced levels of grazing and haymaking are believed to have caused these changes, with increased flooding probably the single most important factor. The increased incidence of flooding is caused by four factors: (1) upstream channel improvements on the Ouse River and better land drainage; (2) increased siltation of waterways on either side of the Washes which reduces their water channel capacity; (3) increased siltation at the outflow of the Washes which slows water flow out of the system; and (4) possible changes in the operation of a sluice which allows water onto the Washes. The vegetation changes have resulted in a reduction of plant species diversity in grazed, hayed and unmanaged Washes, but especially in the unmanaged Washes. They may have also affected ornithological use of the site but this requires further investigation. (Author's abstract)

ASSESSMENT OF BANK SLOPE AS A PREDICTOR OF CONSERVATION STATUS IN RIVER CORRIDORS.
University Coll., Cardiff (Wales). School of Pure and Applied Biology.
M. A. Learner, D. W. Bowker, and J. Halewood.
Biological Conservation BICOBK, Vol. 54, No. 1, p 1-13, 1990. 4 fig, 5 tab, 12 ref.

Descriptors: *Conservation, *Ecology, *Ecosystems, *Rivers, *Stream banks, *Taxonomy, Bank slope, Fauna, Flora, Population density, River Arrow, River Monnow, River Wye, Species composition, Species diversity, Statistical analysis, Wales.

The importance of bank slope as a predictor of conservation status in river corridors was assessed by means of a survey of the taxonomic richness, taxonomic density and relative abundance of aquatic and terrestrial macro-invertebrates, vascular plants and bryophytes in aquatic, marsh, bank and adjacent land habitats at 22 sites on three rivers (River Wye and two of its tributaries, the Rivers Arrow and Monnow) at bank slopes ranging from 3 to 50 degrees. Bivariate and multivariate analyses demonstrated that bank slope was a poor predictor of conservation status in terms of the evaluation criteria employed. However, the taxonomic richness of the flora was positively correlated with the width and height of the bank. There was some indication that narrow banks with steep slopes supported a greater density of plant taxa than wide banks with shallow slopes. The taxonomic richness of the flora was not correlated with that of the fauna. No correlations were found between the taxonomic richness and density on the bank and those on the adjacent land. EFFECTS OF POOL SIZE AND ISOLATION ON AMPHIBIAN COMMUNITIES.
Katholieke Univ. Nijmegen (Netherlands). Dept. of Animal Ecology.
R. Laan, and B. Verboom.
Biological Conservation BICOBK, Vol. 54, No. 3, p 251-262, 1990. 2 fig, 4 tab, 14 ref.

Descriptors: *Amphibians, *Aquatic habitats, *Ecology, *Ecosystems, *Species diversity, Fauna, Forests, Habitats, Isolation, Limburg, Pools, Regression analysis, Species composition, The Netherlands.

An investigation of the presence of amphibians was carried out in 38 old and 39 recently constructed pools in the South of Limburg, The Netherlands. In order to assess possible effects of pool size and isolation on the number of species, characteristics of the pools and the surrounding landscape were analyzed by means of stepwise multiple regression analysis. In all analyses habitat variables concerning the pool were corrected for. Significant effects of pool size were found for old pools only. In both old and new pools species number turned out to be positively influenced by the vicinity of a wood. Woodland is considered here as an element increasing the connectivity of a landscape and as a part of the land habitat of amphibians. Pool age was the best predictor of species number in the new pools. The three most abundant species displayed differences in colonization rate. These differences turned out to be related to their abundance. (Author's abstract)

DISTRIBUTION OF CALIFORNIA STREAM FISHES: INFLUENCE OF ENVIRONMENTAL TEMPERATURE AND HYPOXIA.
California Univ., Davis. Dept. of Wildlife and Fisheries Biology.
J. J. Cech, S. J. Mitchell, D. T. Castleberry, and M. McEnroe.
Environmental Biology of Fishes EBFID3, Vol. 29, No. 2, p 95-105, October 1990. 1 fig, 4 tab, 35 ref.

Descriptors: *Dissolved oxygen, *Ecology, *Environmental effects, *Fish, *Fish physiology, *Stream fisheries, *Water temperature, California, Fish populations, Habitats, Metabolism, Streams.

Metabolic rates of seven fish species were used to assess the importance of temperature and dissolved oxygen as factors affecting the longitudinal distributions of stream fish within California drainages. Metabolic rates of all species generally increased at higher acclimation temperatures and with abrupt temperature increases. In response to low dissolved oxygen, four species showed no change in metabolic rates up to a threshold temperature where hypoxia-induced metabolic depression was apparent. These threshold temperatures were near the lethal temperatures for each species. In contrast, two species showed metabolic depressions at every temperature, whereas one showed no depression at any temperature. In general, species occupying similar longitudinal positions in California streams behaved similarly in their metabolic responses. For most species, there was good correspondence between metabolic response and relevant field observations of occurrence. In cases where the analysis of metabolic rates predicted species presence in waters where they did not exist, other abiotic factors, such as flow rate, or biotic factors, such as predation or competition must be considered. (Author's abstract)

COONGIE LAKES CONTROL ZONE--A MAP AND NOTE FOR THE SURFACE GEOLOGY AND TERRAIN.
G. W. Krieg, and R. A. Callen.
Mines and Energy Review South Australia, No. 157, p 59-61, 1990. 2 figs, 4 ref.

Descriptors: *Australia, *Habitats, *Lakes, *Maps, *Wetlands, Arid lands, Coongie Lakes, Cooper Creek, Innamincka Station Regional Reserve, Surficial geology, Topology.

The Coongie Lakes wetland, fed by Cooper Creek, is an almost permanent, freshwater, shallow lake system extending for over 50 km in South Australia's arid northeastern desert dunefields. This unique habitat, which supports an abundant aquatic and bird life, and a fringing eucalypt wood is protected under the National Parks and Wildlife Act as part of the Innamincka Station Regional Reserve, while allowing other economically important activities to proceed. An accompanying map, shows the surface geology and terrain, differentiates the main landscape units, and was compiled to assist land management of the area. Research into the sedimentology and hydrodynamics of the Coongie Lakes system would be warranted if any major surface or subsurface extraction of materials is contemplated. (Author's abstract)

SENSITIVITY ANALYSIS OF NINE DIVERSITY AND SEVEN SIMILARITY INDICES.
National Park Service, Fort Collins, CO. Water Resources Div.
T. P. Boyle, G. M. Smillie, J. C. Anderson, and D. R. Beeson.
Research Journal of the Water Pollution Control Federation JWPFA5, Vol. 62, No. 6, p 749-762, September/October 1990. 22 fig, 1 tab, 17 ref.

Descriptors: *Aquatic ecosystems, *Limnology, *Monitoring, *Sensitivity analysis, *Species diversity, *Water quality, Ecology, Population density, Simulation analysis, Species composition, Statistical analysis.

Sixteen indices commonly used to assess the status of aquatic communities in water quality studies were evaluated using computer simulation techniques to determine specific index responses. Three communities of different initial structure (19, 3 and 83 species) were generated using the logonormal equation. Each community was then perturbed in three ways: common species disproportionally reduced, all species proportionally reduced, and rare species disproportionally reduced. The behavior of the indices was analyzed graphically and differential response due to initial community structure and type of community change was documented. The results indicated that the response of the community level indices was dependent on the initial structure of the community and the manner in which the community was perturbed. In general, community level indices at the present stage of technical development may give very misleading biological interpretations of the data they are intending to summarize. Diversity indices, in particular, should not be used except in concert with other indices. Further research is recommended to determine the applicability of the specific indices to different aquatic ecosystems. (MacKeen-PTT)

SEDIMENT OXYGEN DEMAND MODEL: METHANE AND AMMONIA OXIDATION.
Manhattan Coll., Bronx, NY. Environmental Engineering and Science Program.
D. M. Di Toro, P. R. Paquin, K. Subburamu, and D. A. Gruber.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 945-986, 1990. 13 fig, 5 tab, 50 ref, 2 append.

Descriptors: *Ammonia, *Methane, *Model studies, *Sediment chemistry, *Sediment oxygen demand, *Water pollution control, Chemical analysis, Lake sediments, Mathematical analysis, Mathematical models, Oxidation, Stream sediments.

A model of sediment oxygen demand (SOD) is presented that relates SOD to the extent of oxidation of dissolved methane and ammonia generated in the anaerobic zone of the sediment of lakes and streams. The fluxes of dissolved methane and ammonia from the sediment to the overlying water, as well as methane and nitrogen gas fluxes that escape as bubbles, are included in the model. The three model parameters--the dissolved methane mass transfer coefficients and the two oxidation rate parameters--were estimated from laboratory and field data sets. The effect of overlying water dissolved oxygen and temperature was also examined. The importance of the gas fluxes and their quantitative relationship to SOD was established. Any field program that includes the measurement of SOD should also include the measurement of nitrogen and methane fluxes as well. The model is limited to freshwater sediments since the oxidation of sulfides is not included. The contribution from the respiration of benthic macro fauna is also not incorporated. AQUATIC AND CERTAIN WETLAND VASCULAR VEGETATION OF REELFOOT LAKE, 1920S-1980S. III. SUBMERSED MACROPHYTES.
Tennessee Univ. at Martin.
J. W. Henson.
Journal of the Tennessee Academy of Science JTASAG, Vol. 65, No. 4, p 107-111, 1990. 1 fig, 1 tab, 23 ref, Tennessee Wildlife Resources Agency Contracts ID 2282, ID 2539, and ID 2611.

Descriptors: *Aquatic plants, *Limnology, *Macrophytes, *Reelfoot Lake, *Submerged aquatic plants, *Wetlands, Ecosystems, Hornwort, Pondweeds, Seasonal variation, Species composition, Tennessee, Water level, Waterlilies, Waterweeds.

Ceratophyllum demersum L. has been known from Reelfoot Lake since the early 1920s and was the predominant submersed macrophyte from 1933 through the 1950s. In 1983 it was dominant during the summer and early fall months. Potamogeton crispus L., an exotic, rapidly became spring dominant soon after its introduction in 1959. Life cycle differences reduce competition between these plants. The 1983 distributions of 4 other less-prevalent species, P. pectinatus L., P. pusillus L., Elodea nuttallii St John, and Cabomba carloiniana Gray, appeared to be similar to those of the early 1940s but abundances likely had been reduced. Fluctuations of all had occurred over the years. Rare species in 1983, previously occurring in quantity were: P. nodosus Poir., Najas guadalupensis Magnus., Heteranthera dubia MaxM., Ranunculus Sabellaris Raf., and Zannichellia palustris L. At last since 1983, Utricularia biflora Lam. has persisted in numerous shallow pools as sparse plants within other dense vegetation. Elevated mean lake levels during the last four decades, and species competition, are considered primary factors contributing to the reduction of less dominant species. Fluctuations of submersed species have occurred since the White Amur (Ctenopharyngodon idella Val.) was released into the lake during the winter of 1983-84. (See also W91-02582) (Author's abstract)
W91-02581

AQUATIC AND CERTAIN WETLAND VASCULAR VEGETATION OF REELFOOT LAKE, 1920S-1980S. IV. SEASONALLY EMERGENT MACROPHYTES.
Tennessee Univ. at Martin.
J. W. Henson.
Journal of the Tennessee Academy of Science JTASAG, Vol. 65, No. 4, p 112-116, 1990. 2 tab, 27 ref. Tennessee Wildlife Resources Agency Contracts ID 2282, ID 2539, and ID 2611.

Descriptors: *Aquatic plants, *Emergent aquatic plants, *Macrophytes, *Reelfoot Lake, *Water pollution effects, *Wetlands, Herbicides, Limnology, Marshes, Pesticides, Primrose, Seasonal variation, Smartweed, Species composition, Species diversity, Swamps, Tennessee, Water level, Waterlilies.

Seasonally emergent macrophytes of Reelfoot Lake were surveyed from 1983-88. These nonpersistent marshes are compared and contrasted with those reported for earlier periods. Since about 1943, the foremost abiotic influence upon vegetational change is believed to have been higher, average water depths. Previous herbicide applications are thought to have exerted minimal effects upon the status of nonpersistent marshes of the 1980s. Two anchored species have been continually dominant: Nelumbo lutea Pers. and Nuphar luteum subsp. macrophyllum Beal. Relatively pure strands of both were more extensive 30-60 years ago. Nymphaea odoata Ait, has increased since the 1930s, likely because of reduced competition from the dominant anchored species. Concurrently, the earlier shallow-water habitat of Brasenia schreberi Gmel. has been essentially eliminated by thick stands of both seasonally emergent and submersed species. The following three species have spread into the expanding swampy areas over the past 40 years: Polygonum densiforum Meisn., Ludwigia peploides (HBK) Raven and Limnobium spongia (Bosc.) Steud. In shallow water, nonpersistent marshes, P. densiflorum promotes the slow succession to tree swamps. The small floating macrophytes (Duckweeds, Lemna minor L. and Spirodela polyrhiza (L.) Schleid.; Watermeals, Wolffia spp.; and Mosquito Fern, Azolla caroliniana L.) have been abundant and widespread within nonpersistent marshes and swamps for many years. Justicia americana (L.) Vahl and Hydrocotyle ranunculoides L. f., recent introductions and still localized on the lake, have the potential for spreading into other lake selections. (See also W91-02581) (Author's abstract)

RESPONSE OF THE MICROBIAL LOOP TO PHYTOPLANKTON SPRING BLOOM IN A LARGE PREALPINE LAKE.
Konstanz Univ. (Germany, F.R.). Limnological Inst.
T. Weisse, H. Muller, R. M. Pinto-Coelho, A. Schweizer, and D. Springmann.
Limnology and Oceanography LIOCAH, Vol. 35, No. 4, p 781-794, June 1990. 6 fig, 3 tab, 62 ref. Deutsche Forschungsgemeinschaft Grant I/63 699, and Brazilian Ministry of Education Grant CAPES PROC. 386/86.2.

Descriptors: *Algal blooms, *Limnology, *Mountain lakes, *Phytoplankton, Bacteria, Biomass, Food chains, Germany, Lake Constance, Microbiological studies, Phosphates, Population dynamics, Primary productivity, Seasonal variation.

Abundance, biomass, production, and grazing loss rates of phytoplankton, free-living bacteria, and Protozoa were assessed during an intense spring phytoplankton bloom in prealpine Lake Constance (Bodensee). More than 50% of the primary production was channeled through the microbial loop. Bacteria and ciliates responded rapidly to increasing phytoplankton biomass and production. Maximal growth rates of bacteria and protozoa were slightly lower than those of the dominating phytoplankton species. Averaged over the spring bloom, bacterial C amounted to 21% of phytoplankton C, and bacterial production to 18% of particulate primary production. An increase of heterotrophic flagellate populations was prevented by grazing within the microbial loop, probably by the feeding impact of ciliates. Although ciliates controlled flagellate production, they satisfied their own food demand by feeding on algae, and consumed 14% of primary production. Metazoan microzooplankton (copepod nauplli and rotifers) removed 7% of the phytoplankton production. Herbivorous metazooplankton ingested slightly less. Therefore the phytoplankton bloom was not terminated by excess grazing. PO4 depletion and subsequent sedimentation was most likely the prime cause for the termination of the spring bloom. (Author's abstract)

PLANKTONIC COMMUNITY STRUCTURE DETERMINES THE FATE OF BACTERIAL PRODUCTION IN A TEMPERATE LAKE.
New York Botanical Garden, Bronx, NY. Inst. of Ecosystem Studies.
M. L. Pace, G. P. McManus, and S. E. G. Findlay.
Limnology and Oceanography LIOCAH, Vol. 35, No. 4, p 795-805, June 1990. 4 fig, 3 tab, 60 ref. NSF Grant BSR88-05893.

Descriptors: *Bacteria, *Limnology, *Plankton, *Primary productivity, *Species composition, Daphnia, Ecosystems, Food chains, Microbiological studies, New York, Phytoplankton, Rotifers, Seasonal variation, Upton Lake.

An examination was made of the fate of planktonic bacterial production and the balance between bacterial growth and grazing mortality in the surface waters of Upton Lake, New York. Growth rates were measured by the incorporation of (3-H)thymidine into DNA. Grazing rates on bacteria were determined with small cells produced by a mutant strain of E. coli and made either florescent or radioactive to monitor feeding. Bacterial community turnover times calculated from either growth or grazing rates ranged from 1.5 to 16 days. On the basis of these data and the results of 29 other studies, most bacterial communities appear to have turnover times substantially > 1 day. The measurements of feeding rates on bacteria frequently exceeded estimates of growth. Limitations of precision and doubts about the accuracy of methods make attempts to balance measurements of bacterial growth and grazing with current techniques unrealistic. The fate of bacterial production depends on planktonic community structure. Flagellates were the primary consumers of bacteria in winter and fall. At other times, Daphnia galeata consumed most of the bacterial production. Ciliates and rotifers were never important bacterial grazers. In Upton Lake, large populations of daphnia effectively break the microbial loop and funnel bacterial production to higher consumers. (Author's abstract)

TYPE OF SUSPENDED CLAY INFLUENCES LAKE PRODUCTIVITY AND PHYTOPLANKTON COMMUNITY RESPONSE TO PHOSPHORUS LOADING.
Hampton Univ., VA. Center for Marine and Environmental Studies.
B. E. Cuker, P. T. Gama, and J. M. Burkholder.
Limnology and Oceanography LIOCAH, Vol. 35, No. 4, p 830-839, June 1990. 8 fig, 1 tab, 23 ref. EPA Grant R813315-01-0.

Descriptors: *Aquatic productivity, *Clays, *Limnology, *Phosphorus, *Phytoplankton, *Suspended sediments, Algae, Biomass, Kaolinite, Lake sediments, Montmorillonite, North Carolina, Primary productivity, Sediment chemistry, Turbidity.

The effects on phytoplankton and limnetics of two different types of suspended sediments, and their interactions with P loading, were tested in a small North Carolina piedmont lake. Limnocorrals were used in a complete, triplicated six-treatment, blocked design. Treatments were loaded with P, kaolinitic clay (K), K+P, montmorillonitic clay (M) and M+P. M caused more turbidity and stayed in suspension longer than K. Consequently, the light dependent parameters, net community

productivity (NCP), chlorophyll concentration, and algal density were lowest in the M and highest in the P treatment. Combined P and K loading promoted clearing for both sediments and mitigated their effects on algal densities and NCP. Flagellated algae and nonfilamentous cyanophytes dominated the control community. The P treatment had blooms of Anabaena. Without fertilization, both clays resulted in sparse, flagellate-dominated communities. The M+P community, like that of the P treatment, was dominated by Anabaena, but total algal densities were suppressed. In contrast, the K+P community lacked Anabaena and was similar to the control in algal quantity and composition. (Author's abstract)

SULFUR STORAGE AND ALKALINITY GENERATION IN NEW ENGLAND LAKE SEDIMENTS.
Marine Biological Lab., Woods Hole, MA. Ecosystems Center.
A. E. Giblin, G. E. Likens, D. White, and R. W. Howarth.
Limnology and Oceanography LIOCAH, Vol. 35, No. 4, p 852-869, June 1990. 9 fig, 2 tab, 71 ref. NSF Grant BSR 86-15191.

Descriptors: *Acid rain, *Acid rain effects, *Alkalinity, *Lake sediments, *New England, *Path of pollutants, *Sulfur, *Water pollution sources, Pyrite, Sediment contamination, Sulfates, Sulfides, Water quality.

Measurements of the rates of burial and forms of reduced S in lake sediments were made to evaluate the importance of SO4 reduction to the alkalinity budget of several New England lakes. The contribution of dissimilatory SO4 reduction to alkalinity generation in these lakes was estimated conservatively to range from 1 to 75 meq/sq m/yr. The contribution of both assimilatory and dissimilatory SO4 reduction ranged from 10-159 meq/sq m/yr. For lakes with water residence times on the order of years, SO4 reduction can be important in controlling lake water alkalinity. Substantial quantities of inorganic reduced S were found in sediments of nearly all lakes studied. The majority was present as pyrite. In most lake concentrations of inorganic reduced S were higher in sediments deposited in the last 85 yr when compared to older sediments. In contrast, the ratio of C to organic S showed no consistent trend with depth in most lakes. It appears that in these lakes, most of the sulfide produced from SO4 reduction is stored primarily as inorganic forms rather than as C-bonded S. In lakes with highly organic sediments and low Fe concentrations, it was found that a considerable portion of the sedimentary Fe was present as ferrous sulfides. If these lakes were typical, alkalinity generation by reduced S storage in lakes with organic rich sediments in the northeastern US already may be limited by Fe availability. (Author's abstract)

Tellus TELLAL, Vol. 42A, No. 5, p 615-626, 1990. 7 fig, 2 tab, 17 ref. Swedish Natural Science Research Council Contract NFR G-4768.

Descriptors: *Lake Vattern, *Limnology, *Seiches, *Sweden, Lake morphology, Mathematical equations, Mathematical studies, Sensitivity analysis, Topography, Water level.

A newly developed perturbation technique for resolving Chrystal's classical seiche problem has been applied to Vattern, a deep and elongated lake in central Sweden. Theoretical predictions of the standing wave periods were compared to those from the spectral analysis of a 3-month water level record. The results for the gravest-mode seiche were found to be in good agreement, whereas the second and third mode showed a systemic deviation from the observations. A sensitivity analysis of the computational procedure indicates that this discrepancy can most likely be ascribed to insufficient knowledge of the detailed topography of the lake. (Author's abstract)

Descriptors: *Acid rain, *Acidification, *Climatic changes, *Ecology, *Ecosystems, *Model studies, Data acquisition, Data interpretation, Data requirements, Future planning, Model testing.

Recent interest in ecosystem modelling emerges from large-scale problems such as acid deposition or climatic change. Knowledge about future states of ecosystems can be based on management experience and scientific observation. The former cannot be extrapolated outside the range of past variations in boundary conditions. Thus, the long-term changes in the chemical or physical climate require the identification of key-processes for successful model predictions. This scientific task is implicitly based on assumptions about the appropriate scale of integration in space and time. No scientific discipline exists by which these assumptions can be formally derived at the ecosystem level. The example of modeling soil and water acidification is used to discuss the possible consequences of a technological or a scientific perception of the problem posed, respectively. These approaches often suffer from inconsistent treatment of their basic assumptions in the first case, and from lack of theory in the latter case. On the basis of the available data and theory the question posed remains undecided. However, there is a risk that focusing ecosystem research on technological perception becomes a self-fulfilling prophesy. (Author's abstract)

SOIL WATER IN THE RIPARIAN ZONE AS A SOURCE OF CARBON FOR A HEADWATER STREAM.
University Coll. of North Wales, Bangor. School of Biological Sciences.
D. M. Fiebig, M. A. Lock, and C. Neal.
Journal of Hydrology JHYDA7, Vol. 116, No. 1/4, p 217-237, August 1990. 6 fig, 2 tab, 53 ref.

Descriptors: *Dissolved organic carbon, *Geochemistry, *Headwaters, *Soil water, *Stream banks, *Streams, *Surface-groundwater relations, Nitrogen, Solute transport, Streambeds, Wales.

A comparison of the organic chemistries of soil waters in the riparian zone and an adjacent stream at an upland site in mid-Wales was made over a period of one year. Dissolved organic carbon (DOC) distributions in riparian soil waters showed little temporal or spatial consistency, but concentrations almost always exceeded those in the stream (mean = 9.4 and 2.1 mg/l, respectively). Three major hydrological flow paths in the riparian zone were inferred by correlating dynamics of the organic chemistry, as well as inorganic nitrogen (ammonium and nitrate), between sampling points. A lack of any dynamic relationship between organic concentrations in saturated throughflow of the stream bank and the stream suggested an efficient immobilization of this soil water DOC within the streambed, prior to its discharge into the stream. Correlations for both DOC and inorganic N between the stream bank unsaturated zone and the stream suggested that, at higher flows, this soil water input could directly influence the stream. A high degree of correlation between soil water of the forest edge (6 m from the stream) and the stream suggested that some form of macroporous transfer of soil water from further back in the riparian zone would also directly influence the stream. It is concluded that the riparian zone can contribute substantial amounts of DOC to a stream ecosystem, and that the streambed must be a key area of chemical reactivity where much of this material is initially processed. PRODUCTION OF DISSOLVED DNA, RNA AND PROTEIN BY MICROBIAL POPULATIONS IN A FLORIDA RESERVOIR.
University of South Florida, St. Petersburg. Dept of Marine Science.
J. H. Paul, W. H. Jeffrey, and J. P. Cannon.
Applied and Environmental Microbiology AEMIDF, Vol. 56, No. 10, p 2957-2962, October 1990. 4 fig, 29 ref. National Science Foundation Grant 8601570.

Descriptors: *Biochemistry, *Limnology, *Microorganisms, *Nucleic acids, *Radioactive tracers, *Reservoirs, Algal growth, Bacterial physiology, Carbon fixation, Carbon radioisotopes, Florida, Macromolecules, Phosphorus radioisotopes, Phytoplankton, Proteins.

Production of dissolved macromolecules by ambient autotrophic and heterotrophic microbial populations was measured in a eutrophic Florida reservoir by in situ labeling with various radioactive substrates. When tritiated thymidine was used as the precursor, production of labeled dissolved DNA, RNA and protein was observed. The rate of production of labeled dissolved macromolecules was 3.1%, the rate of cellular incorporation of tritiated thymidine and the production of dissolved DNA represented 2.3% the rate of cellular DNA incorporation. Microautotrophic populations labeled with 14-C labeled sodium carbonate produced dissolved RNA and protein at rates of 0.1 and 0.11 microg of C/L/hr, or 1.8% the total r

of carbon fixation, with no measurable dissolved DNA production. In an attempt to specifically label phytoplankton DNA, samples were incubated with tritiated adenine or intracellular 32-P in the presence and absence of the photosynthetic inhibitor 3-(3,4-dichlorophenyl)-1,1-dimethylurea (DCMU). Although DCMU inhibited 14-C fixation by approximately 99%, this antimetabolite had only a slight effect on tritiated adenine incorporation and no effect on 32-Pincorporation into cellular macromolecules. Significant amounts of dissolved DNA were produced in both tritiated adenine and intracellular 32-P incubations, but again DCMU had no effect on the production rates. These results indicate that actively growing populations of both phytoplankton and bacterioplankton produced dissolved RNA and protein, while only active bacterioplankton produced measurable quantities of dissolved DNA. Dead or senescent phytoplankton may have produced dissolved DNA, but would not be measured in the relatively short incubations used. (Author's abstract)

Descriptors: *Blackwater streams, *Ecosystems, *Organic matter, *River systems, Carbon cycle, Cycling nutrients, Dissolved solids, Food chains, Microorganisms, Model studies, Suspended sediments.

Streams are a vital natural resource, providing fresh water to support a growing human population as well as transport and treatment for wastewater. Blackwater rivers contain a low level of suspended sediments but a high concentration of dissolved organic matter. Basin-wide perspectives of rivers indicate that much of the degradation of organic matter added to streams is occurring in moderate-size channels rather than in headwaters, despite the headwaters' greater length. An expanded spatial perspective is necessary to investigate element cycling in lotic ecosystems where cycles are continuously depleted downstream by flowing water. The microbial loop is an effective pathway for recycling inorganic nutrients, as well as providing food for consumers and organic matter for nutrient regeneration. The lotic food web can be viewed as a mosaic of consumers and producers, located in the water column, the stable substrates of the blackwater river, and the unstable substrates (such as sandy sediments). Quantification is needed of the rates of exchange of nutrients and organic matter between the different components of the stream ecosystem, as well as an assessment of factors controlling these links. Empirical and modeling studies are needed to assess the significance of the microbial food web as a pathway of organic carbon transfer and nutrient spiraling in flowing waters. (Brunone-PTT)

Descriptors: *Cypress swamps, *Ecological effects, *Land use, *Water level fluctuations, *Wetlands, Competition, Evapotranspiration, Flooding, Nutrients, Population density, Population dynamics, Primary productivity, Seasonal variation, Water table.

In a world with a rapidly increasing population and a shrinking resource base, uncontroversial land use decisions are becoming increasingly difficult. Wetlands are particularly vulnerable because they often represent the only undeveloped land in an area. Cypress swamps provide a variety of benefits, and are useful for demonstrating the kinds of landuse conflicts that may arise. Bald cypress trees are common where flowing water brings in nutrients and ameliorates reducing conditions in the soil; pond cypress trees are common in small stillwater swamps. Water level fluctuates in all cypress swamps, and cypress seeds will not germinate under standing water. High water is necessary to reduce competition from more rapidly growing vegetation. Gross primary productivity in cypress swamps is closely related to the rate of nutrient inflow, and aboveground net primary productivity tends to be highest in swamps with intermediate hydroperiods. Because the water level in a cypress pond is generally continuous with the water table in the surrounding landscape, groundwater flows into the swamp when heavy rainfall raises the water table, and groundwater is recharged at the end of the rainy season when water tables drop more rapidly than water levels in the ponds. In addition, cypress ponds seem to have a lower evapotranspiration rate than surrounding ecosystems, provide flood and water quality control, and serve as a source of wood. Decisions about use of an individual swamp must consider its regional importance. The time course of succession must be considered, as well as the possible importance of fire to a cypress swamp. There are often difficulties in estimating the bioavailability of essential nutrients and energy sources for aquatic microorganisms involved in mediating key sedimentary biotransformations. In order to estimate rates of sulfate reduction and putrefaction in sedimentary hydrogen sulfide production, a kinetic bioassay procedure was utilized to confirm the concentrations of hydrogen sulfide precursors determined by standard analytical procedures. S35-labeled sulfate and cysteine were added separately to freshwater lake sediment which had been transferred to plastic disposable syringes and incubated at 10 C for 2 h. Substrate depletion during the 2 h incubation ranged from approx. 1 to 5%. Final labeled plus unlabeled concentrations of sulfate and cysteine varied from 4.3 to 12.3 and 2.2 to 5.6 mg S/L, respectively. Precision of the method was +/-15%. The results were suggestive but inconclusive that sulfide production via sulfate reduction and putrefaction adhere to the Michaelis-Menten kinetic model. Nevertheless, the kinetic bioassay procedure of Wright and Hobbie appears to be useful in estimating substrate bioavailability for cysteine and sulfate and perhaps other sedimentary substrates. In addition, the method permits reliable tracer estimates of sulfide production in freshwaters with low sulfate concentrations which might otherwise not be possible. (White-Reimer-PTT)

Ephemeral saline lakes form along the eastern shore of Spencer Gulf, in semiarid southern Australia, where beach ridges isolate areas of the high supratidal zone. Lacustrine sediments studied contain abundant discoidal gypsum. Isotope distributions and ion ratios indicate that groundwater from landward of and within the lake is non-marine in origin. The marine-terrestrial groundwater interface is mobile; after heavy rain, continental-derived brines flow seaward as far as the high intertidal zone. Within the lake, seasonal changes result in alternate desiccation and flooding by mildly acidic and oxidizing waters. The consequent variability in salinity and redox conditions is inimical to sustained biological activity or sulfide preservation. During dry periods, a halite crust forms on the surface and, as anaerobic conditions and bacterial sulfate reduction are established, iron sulfides precipitate in the vadose sediments. However, when water table levels rise, cyanobacteria colonize wetted surface sediments and the iron sulfides become oxidized. Mobilization of Zn indicates that metals can be transported in the oxidized brines, but such an environment would not favor their preservation as sulfides. The lake is most notable for its gypsum formation and can be differentiated from other well-documented sites in that both the water and the sulfate ions have continental signatures despite the proximity to marine-influenced zones. These coastal, gypsiferous, ephemeral lakes are more akin to a continental playa but with some aeolian influences, and thus extend the spectrum of coastal sabkha-like environments, particularly as a consequence of the semiarid climate. SEASONAL DYNAMICS IN METHANE EMISSIONS FROM THE AMAZON RIVER FLOODPLAIN TO THE TROPOSPHERE.
Washington Univ., Seattle. School of Oceanography.
A. H. Devol, J. E. Richey, B. R. Forsberg, and L. A. Martinelli.
Journal of Geophysical Research (D) Atmospheres JGRDE3, Vol. 95, No. 10, p 16,417-16,426, September 10, 1990. 5 fig, 3 tab, 64 ref. NSF Grant Nos. BSR-83-16359 and BSR-87-18423; NASA Grant No. NAGW-1066.

Descriptors: *Amazon River Basin, *Atmospheric chemistry, *Flood plains, *Methane, *Seasonal variation, Air pollution, Annual floods, Aquatic plants, Flooding, Lakes, Macrophytes, Tropical regions, Water level.

Methane fluxes to the troposphere from the three principal habitats of the floodplain of the Amazon River main stem (open waters, emergent macrophyte beds, and flooded forests) were determined along a 1700-km reach of the river during the low water period of the annual flood cycle (November-December 1988). Overall, emissions averaged 68 mg CH4 and were significantly lower than similar emissions determined previously for the high water period, 184 (+/-41) mg CH4/sq m/d. This difference was due to significantly lower emissions from floating macrophyte environments. Low water emissions from open waters and flooded forest

areas were not significantly different than at high water. A monthly time series of methane emissions from eight lakes located in the central Amazon Basin showed similar results. Average annual emission from the lakes was 125 (+/-28) mg CH4/sq m/day. Methane emissions from lakes were significantly higher during the high water period, again, primarily due to an increase in emissions from macrophyte habitats. The data were used to calculate a seasonally weighted annual emission to the troposphere from the Amazon River main stem floodplain of 5.1 Tg/yr which indicates the importance of the area in global atmospheric chemistry. METHANE FLUX FROM THE AMAZON RIVER FLOODPLAIN: EMISSIONS DURING RISING WATER.
College of William and Mary, Williamsburg, VA. Dept. of Biology.
K. B. Bartlett, P. M. Crill, J. A. Bonassi, J. E. Richey, and R. C. Harriss.
Journal of Geophysical Research (D) Atmospheres JGRDE3, Vol. 95, No. 10, p 16,773-16,788, September 20, 1990. 8 fig, 4 tab, 66 ref.

Descriptors: *Amazon River Basin, *Atmospheric chemistry, *Flood plains, *Methane, *Seasonal variation, Air pollution, Aquatic plants, Fluctuations, Tropical regions, Water level, Wetlands.

During April and May 1987, an extensive methane flux data set from Amazonian wetland habitats was collected during the wet season as river water levels were high and rising. This work extended measurements made in the dry season of 1985, when water levels were falling. Comparisons between these two data sets allows the estimation of the amount of seasonal variability in this globally significant source of tropospheric methane. A total of 284 flux measurements were made in the three primary floodplain environments of open water lakes and channels, floating grass mats, and flooded forests, along approximately 1500 km of the central floodplain. Emissions (means and standard errors) were 74 +/-14 mg CH4/sq m/d (open water), 201 +/-35 mg CH4/sq m/d (grass mats), and 126 +/-20 mg CH4/sq m/d (flooded forests). These values were not significantly different from the majority of those from 1985, due in part to the high variability in flux seen at both times. Although ebullition was a significant component of methane emissions at both periods, the frequency of bubbling and its contribution to total flux was lower during the period of rising water than of falling water. A prominent diurnal pattern in atmospheric methane concentrations was observed, with minimum levels of about 1.75 ppm at midday and a maximum of 2.12 ppm at around midnight. Given the relatively small seasonal changes observed in flux at the two stages of the rivers hydrographic curve, earlier estimates of regional methane flux remain largely unchanged. Revision of global estimates of wetland methane sources based on these tropical data and recently published figures for northern peatlands indicated that tropical wetlands may be more important than previously suggested, but that wetland sources overall remain at approximately 110 Tg/yr. Water Resources Research WRERAQ, Vol. 26, No. 10, p , October 1990. 14 fig, 40 ref. Department of Energy Grant DEFG02-85ER60304.

Descriptors: *Climatic changes, *Hydrologic cycle, *Lake evaporation, *Oregon, *Water level fluctuations, Closed basins, Eddy diffusion, Evaporation, Hydrologic models, Water temperature.

The hydrologic balance of a lake represents a direct response to prevailing climatic conditions in unregulated lake basins. Evaporation is a primary path for water loss from most lakes; therefore in order to assess the relation between climatic variations and fluctuations in the size of a lake a method for estimating evaporation rates that is sensitive to climatic variations is required. A physically based eddy diffusion model can stimulate the seasonal variation in lake temperature and evaporation. Because no lake-specific fitting of the parameters of the model is necessary, the model can be used to simulate evaporation in studies of climate change and lake hydrology in a variety of settings. The eddy diffusion model is used to simulate evaporation for input to a simple lake level model that is applied to reconstruct recent fluctuations in the level of Harney-Malheur Lake, in the high desert of southeastern Oregon, caused by climatic variations. Beginning in 1982, an increase in effective moisture throughout the Harney-Malheur basin caused the lake to rise over 2 m and attain a depth of more than 4 m during 1984 and 1985. The meteorologic input data for the thermal model and the hydrological data for the lake level model either were obtained from observations or were estimated. Monthly values of the meteorological data were fitted with cubic splines to derive daily input values. The observed fluctuations in lake level were accurately reproduced by the lake level model. Because the model is sensitive to the climatic input variables, it can provide a tool for investigating the response of lake level to climate change. (Author's abstract)

Periphyton communities represent potentially excellent candidates for assessing the recovery of lotic ecosystems after disturbance. These communities are ubiquitous, relatively easy to sample and measure (in terms of total community biomass), have short generation times, and may influence the recovery rates of higher trophic levels. The first section of the article analyzes how site availability, species availability, and differential species performance influence periphyton successional dynamics. This background information provides a foundation for understanding how periphytic organisms respond after a disturbance. The second section of the article analyzes how periphyton communities respond to four different types of disturbance (flood events, dessication, organic nutrient enrichment, and toxic metal exposure). Although data are limited, it is concluded that the fast growth rates and short generation times of periphytic organisms, coupled with their flexible life history strategies and good dispersal ability, allow lotic periphyton communities to recover relatively quickly after a disturbance. In addition, disturbance type and severity, local environmental conditions, and site specific factors also will influence recovery rates. Future research needs include a better understanding of: (1) what periphyton properties would serve as the best index of recovery; (2) whether or not the robustness of this index varies among different environments and different disturbances; (3) interactions between autotrophs and heterotrophs within the periphyton mat, particularly with respect to nutrient cycling; (4) competitive interactions among organisms; (5) functional redundancy of organisms; and (6) the influence of the riparian zone and channel geomorphology on periphyton recovery rates. J. B. Wallace.
Environmental Management EMNGDC, Vol. 14, No. 5, p 605-620, 1990. 3 fig, 1 tab, 135 ref. NSF Grant Nos. BSR83-16082, BSR87-18005, and BSR85-16497.

Descriptors: *Ecosystems, *Habitat restoration, *Lotic environment, *Macroinvertebrates, *Rehabilitation, *Stream biota, *Water pollution effects, Ecological effects, Ecotoxicology, Life history studies, Pesticides, Recolonization, Toxicity.

Ecosystem disturbances produce changes in macrobenthic community structure (abundances, biomass, and production) that persist for a few weeks to many decades. Examples of disturbances with extremely long-term effects on benthic communities include contamination by persistent toxic agents, physical changes in habitats, and altered energy inputs. Stream size, retention, and local geomorphology may ameliorate the influence of disturbances on invertebrates. Disturbances can alter food webs and may select for favorable genotypes (e.g., insecticidal resistance). The introduction of pesticides into lotic ecosystems, which do not result in major physical changes within habitats, illustrate several factors that influence invertebrate recovery time from disturbance. These include: (1) magnitude of original contamination toxicity, and extent of continued use; (2) spatial scale of the disturbance; (3) persistence of the pesticide: (4) timing of the contamination in relation to the life history stages of the organisms; (5) vagility of populations influenced by pesticides and (6) position within the drainage network. The ability of macroinvertebrates to recolonize denuded stream habitats may vary greatly depending on regional life histories, dispersal abilities, and position within the stream network. Although downstream drift is the most frequently cited mechanism of invertebrate recolonization following disturbance in middle and larger-order streams, evidence is shown which shows aerial recolonization to be potentially important in headwater streams. There is an apparent stochastic element operating for aerial recolonization, depending on the timing of disturbance and flight periods of various taxa. Available evidence indicates that recolonization of invertebrate taxa without an aerial adult stage requires longer periods of time than for those that possess winged, terrestrial adult stages (most insects). Innovative, manipulative experiments are needed in order to address recolonization mechanisms of animals inhabiting streams that differ

size, latitude, disturbance frequency and magnitude, as well as the potential influence of early colonists on successional sequences of species following disturbance. (Author's abstract)

ENVIRONMENTAL VARIATION, LIFE HISTORY ATTRIBUTES, AND COMMUNITY STRUCTURE IN STREAM FISHES: IMPLICATIONS FOR ENVIRONMENTAL MANAGEMENT AND ASSESSMENT.
North Dakota Univ., Grand Forks. Dept. of Biology.
I. J. Schlosser.
Environmental Management EMNGDC, Vol. 14, No. 5, p 621-628, 1990. 3 fig, 3 tab, 45 ref. EPA Grant No. R806391; NSF Grants BSR8320371 and BSR8804926.

Descriptors: *Ecosystems, *Environmental policy, *Life history studies, *Stream fisheries, *Water pollution effects, Biological studies, Downstream, Ecological effects, Fish behavior, Monitoring, Temporal distribution, Upstream.

Fishes in midwestern streams of the United States experience strong upstream-downstream gradients in natural environmental variability. Upstream fishes experience greater temporal variability in physical-chemical conditions than downstream fishes. As a whole, upstream species have a shorter life span, smaller body size, and earlier sexual maturity than downstream species. Descriptive studies also suggest upstream species exhibit more rapid recolonization after severe physical disturbance than downstream species, and fish community structure is temporally more variable in upstream than downstream areas. These longitudinal differences in life history characteristics suggest that upstream fish communities will exhibit a more rapid recovery from severe anthropogenic disturbances than downstream fish communities. The greater temporal variability of fish community structure in upstream areas also suggests it will be more difficult in upstream than downstream areas to use fish based indices to distinguish whether subtle changes in environmental quality are due to natural or anthropogenic disturbances. Long-term monitoring of fishes throughout drainage basins is critically needed to establish more precisely the natural range of variation in community structure. Such monitoring will allow regulatory agencies to distinguish, with greater confidence, the influence of anthropogenic disturbances on stream fishes from the influence of natural environmental variation. Spatial and temporal environmental heterogeneity in lotic ecosystems can be quantitatively described and identified with characteristic levels of ecological organization. The long-term pattern of physicochemical variability in conjuction with the complexity and stability of the substratum, establishes a physical habitat template that theoretically influences which combinations of behavioral, physiological, and life history characteristics constitute appropriate ecological strategies for persistence in the habitat. Physical habitat templates and associated ecological attributes differ geographically because of biogeoclimatic processes that constrain lotic habitat structure and stability, and that influence physiochemical variability and disturbance patterns (frequency, magnitude, and predictability). Theoretical considerations and empirical studies suggest that recovery from natural and anthropogenic disturbances also will vary among lotic systems, depending on historical temporal variability regime, degree of habitat heterogeneity, and spatial scale of the perturbation. Characterization of physical habitat templates and associated ecological dynamics along gradients of natural disturbance would provide a geographic framework by predicting recovery from anthropogenic disturbance for individual streams. Description of lotic environmental templates at the appropriate spatial and temporal scale is therefore desirable to test theoretical expectations of biotic recovery rate from disturbance, and to guide selection of appropriate reference study sites for monitoring impacts of anthropogenic disturbance. Historical streamflow data, coupled with stream-specific thermal and substratem-geomorphologic characteristics, are suggested as minimum elements needed to characterize physical templates of lotic systems. DISTURBANCE REGIMES, RESILIENCE, AND RECOVERY OF ANIMAL COMMUNITIES AND HABITATS IN LOTIC ECOSYSTEMS.
North Carolina Univ. at Chapel Hill. Dept. of Biology.
S. R. Reice, R. C. Wissmar, and R. J. Naiman.
Environmental Management EMNGDC, Vol. 14, No. 5, p 647-659, 1990. 7 fig, 114 ref.

Descriptors: *Ecological effects, *Ecosystems, *Habitat restoration, *Habitats, *Lotic environment, *Stream biota, Algae, Aquatic environment, Bank erosion, Channelization, Erosion, Scour, Sediment transport, Sedimentation, Spatial dynamics.

Disturbance regime is a critical organizing feature of stream communities and ecosystems. The position of a given reach in a river basin and the sediment type within that reach are two key determinants of the frequency and intensity of flow induced disturbances. The differences between predictable and unpredictable events are considered; it is suggested that predictable discharge events are not disturbances. The most frequently and predictably disturbed sites can be expected to demonstrate the highest resilience. Spatial scale is an important dimension of community structure, dynamics, and recovery from disturbance. The effects on small patches (< 1 sq m) were compared to the effects of large reaches at the river basin level. At small scales, sediment movements and scour are major factors affecting the distribution of populations of aquatic insects or algae. At larger scales, channel formation, bank erosion, and interactions with the riparian zone that will affect all taxa and processes must be examined. An understanding of stream ecosystem recovery rests on an understanding of the historical, spatial, and temporal background of contemporary disturbance events. (Author's abstract)

ASSEMBLAGE STABILITY IN STREAM FISHES: A REVIEW.
Georgia Univ., Athens. School of Forest Resources.
G. D. Grossman, J. F. Dowd, and M. Crawford.
Environmental Management EMNGDC, Vol. 14, No. 5, p 661-671, 1990. 4 fig, 9 tab, 46 ref. McIntire-Stennis Grant No. GEO-0035-MS.

Descriptors: *Literature review, *Population dynamics, *Stream biota, *Stream fisheries, *Water pollution effects, Baseline studies, Ecological effects, Ecosystems, Fish populations, Species composition, Statistical studies, Variation coefficient.

The stability of nine fish stream assemblages were quantified by calculating coefficients of variation of population size for assemblage members. Coefficients of variation were high and averaged over 96%, indicating that most assemblages were quite variable. Coefficients of variation (CV) estimates were not significantly affected by: (1) years of study, (2) mean abundance, (3) familial classification, or (4) mean interval between collections. Minor regional differences were also detected in CVs. The high variability exhibited by many stream fish assemblages suggest that it may be difficult to detect the effects of anthropogenic disturbances using population data alone; consequently, caution is urged when evaluating the effects of these disturbances. Many long-term studies of the ecological characteristics of undisturbed stream fish assemblages are needed to provide a benchmark against which disturbed systems can be compared. CVs are a better estimator of population/assemblage stability than either Kendall's W or the standard deviation of the logarithms of numerical censuses. This conclusion is based on the following reasons: (1) CVs scale population variation by the mean and, hence, more accurately measure population variability; and (2) this scaling permits the comparison of populations with different mean abundances. Finally, the interpretation of CV values is less ambiguous than either of the aforementioned metrics. (Author's abstract)

REGIONAL FRAMEWORK FOR ESTABLISHING RECOVERY CRITERIA.
NSI Technology Services Corp., Corvallis, OR.
R. M. Hughs, T. R. Whittier, C. M. Rohm, and D. P. Larsen.
Environmental Management EMNGDC, Vol. 14, No. 5, p 673-683, 1990. 7 fig, 44 ref. EPA Contract No. 68-C8-0006.

Descriptors: *Aquatic environment, *Habitat restoration, *Lotic environment, *Resources management, *Stream fisheries, Arkansas, Case studies, Ecosystems, Management planning, Montana, Ohio, Oregon.

Effective assessments of aquatic ecosystem recovery require ecologically sound endpoints against which progress can be measured. Site by site assessments of endpoints and potential recovery trajectories are impractical for water resources agencies. Because of the natural variation among ecosystems, applying a single set of criteria nationwide is not appropriate either. The use of a regional framework for stratifying natural variation and for determining realistic biological criteria was examined. A map of ecoregions, drawn from landscape characteristics, formed the framework of three statewide case studies and three separate studies at the river basin scale. Statewide studies of Arkansas, Ohio, and Oregon, streams demonstrated patterns in fish assemblages corresponding to ecoregions. The river basin study in Oregon revealed a distinct change at the ecoregion boundary; those in Ohio and Montana demonstrated the value of regional reference site for assessing recovery. Ecoregions can be used to facilitate the application of ecological theory and to set recovery criteria for various regions of states or of the country. Such a framework provides an important alternative between site specific and national approaches for assessing recovery rates and conditions. (Author's abstract)

In systems where production is limited by the availability of a nutrient, nutrient input to and recycling within the system is related to the resilience, or speed of recovery, of a system to its steady state following a disturbance. In particular,

it is shown that the return time of the system to a steady state, or the inverse of the resilience, is approximately equal to the mean turnover time of the limiting nutrient in the system. From this relationship it is possible to understand and predict how various properties of food webs and their environments affect resilience. These properties include nutrient input rate, loss rate, size of the detritus compartment, and trophic structure. The effects of these properties on resilience are described by using simple mathematical models. To test model predictions, experimental studies of the response of periphyton-dominated stream ecosystems to disturbance are being conducted on a set of laboratory streams in which nutrient inputs and grazing intensity are regulated at different levels. In streams without snail grazers (low-grazed streams), 90% recirculation of stream water to reduce nutrient inputs resulted in longer turnover times of phosphorous within the stream compared with once-through flow. However, in streams with snail grazers (high-grazes streams) there were no differences in phosphorous turnover time between once-through and partially recirculated treatments. Results on the rate of recovery of periphyton from a flood/scour disturbance to each stream partially support the model prediction of a positive relationship between ecosystem return time and nutrient turnover time within the streams. DISTURBANCE AND RECOVERY OF LARGE FLOODPLAIN RIVERS.
Illinois Natural History Survey, Havana. Stephen A. Forbes Biological Station.
R. E. Sparks, P. B. Bayley, S. L. Kohler, and L. L. Osborne.
Environmental Management EMNGDC, Vol. 14, No. 5, p 699-709, 1990. 5 fig, 1 tab, 30 ref. NSF Grant Nos. BSR-8114563 and BSR-8612107.

Descriptors: *Ecological effects, *Ecosystems, *Flood flow, *Flood plains, *Illinois River, *Mississippi River, *River basins, Annual floods, Aquatic plants, Drought, Flooding, Habitat restoration, Runoff, Suspended sediments, Turbidity, Vegetation.

Disturbance in a river-floodplain system is defined as an unpredictable event that disrupts structure or function at the ecosystem, community or population level. Disturbance can result in species replacements or losses, or shifts of ecosystems from one persistent condition to another. A disturbance can be a discrete event or a graded change in a controlling factor that eventually exceeds a critical threshold. The annual flood is the major driving variable that facilitates lateral exchanges of nutrients, organic matter, or organisms. The annual flood is not normally considered a disturbance unless its timing or magnitude is atypical. The record flood of 1973 had little effect on the biota at a long-term study site on the Mississippi River, but the absence of a flood during the 1976-1977 Midwestern drought caused short and long-term changes. Body burdens of contaminants increased temporarily in key species, because of increased concentration resulting from reduced dilution. Reduced runoff and sediment input improved light penetration and increased the depth at which aquatic macrophytes could grow. Developing plant beds exerted a high degree of biotic control and were able to persist, despite the resumption of normal floods and turbidity in subsequent years. In contrast to the discrete event that disturbed the Mississippi River, a major confluent, the Illinois River, has been degraded by a gradual increase in sediment input and sediment resuspension. From 1958-1961 formerly productive backwaters and lakes along a 320 km reach of the Illinois River changed from clear, vegetated areas to turbid, barren basins. The change to a system largely controlled by abiotic factors was rapid and the degraded condition persists. Greater use should be made of man made or natural disturbances and environmental restoration as opportunistic experiments to measure thresholds and monitor the recovery process. (Lantz-PTT)

ROLE OF REFUGIA IN RECOVERY FROM DISTURBANCES: MODERN FRAGMENTED AND DISCONNECTED RIVER SYSTEMS.
Pacific Northwest Forest and Range Experiment Station, Corvallis, OR. Forestry Sciences Lab.
J. R. Sedell, G. H. Reeves, F. R. Hauer, J. A. Stanford, and C. P. Hawkins.
Environmental Management EMNGDC, Vol. 14, No. 5, p 711-724, 1990. 1 fig, 2 tab, 80 ref. NSF Grant Nos. BSR-8414325, BSR-8508356, BSR-8416127, and BSR-8705269.

Descriptors: *Habitat restoration, *Refugia, *River systems, *Stream biota, Detritus, Flood plains, Research priorities, Riparian vegetation, River channels, Surface-groundwater relationships.

Habitats and environmental factors that convey spatial and temporal resistance and/or resilience to biotic communities that have been impacted by biophysical disturbances may be called refugia. Most refugia in rivers are characterized by extensive coupling of the main channel with adjacent streamside forests, floodplain features, and groundwater. These habitats operate at spatial scales, from localized particles, to channel units such as pools and rifles, to reaches and longer sections, and at the basin level. A spatial hierarchy of different physical components of a drainage network is proposed to provide a context for the different refugia. Examples of refugia operating at different spatial scales, such as pools, large woody debris, floodplains, below dams, and catchment basins are discussed. It is recommend that several research sites be established within ecoregions of the United States. These demonstration sites would be dedicated to understanding processes, including spatial and temporal dynamics of refugia, that control biodiversity and the functional integrity of river ecosystems. RECOVERY PROCESSES IN LOTIC ECOSYSTEMS: LIMITS OF SUCCESSIONAL THEORY.
Arizona State Univ., Tempe. Dept. of Zoology.
S. G. Fisher.
Environmental Management EMNGDC, Vol. 14, No. 5, p 725-736, 1990. 1 fig, 3 tab, 79 ref. NSF Grant Nos. BSR-8406891 and BSR-88-18612.

Descriptors: *Habitat restoration, *Lotic environment, *Stream biota, *Succession, Climates, Ecosystems, Life history studies, Streams.

The concept of succession has a distinguished history in general ecology and has applied to stream ecosystems with some success. Succession in streams is largely secondary, follows initial floristics models, and occurs through a variety of mechanisms. The process is moderately predictable and highly influenced by climatic factors, particularly nutrient chemistry. In desert streams, succession does not result in a climax state. While evidence is slim, succession may not be a significant process in steams of certain types or in certain regions. Successional theory is difficult to apply to spatially heterogeneous, hierarchically organized ecosystems. It also suffers in being only one component of a better integrated concept, that of ecosystem stability, which deals more directly with disturbance and ecosystem resistance in addition to resilience (which encompasses succession). Succession has so suffered from a half century of confusion that a strong case can be made for abandoning the term, at least as it applies in streams, in favor of a broader view provided by the stability theory. (Author's abstract)

Descriptors: *Ecological effects, *Ecosystems, *Habitat restoration, *Lotic environment, *Research priorities, Heterogeneity, Monitoring, Spatial variation, Species diversity, Stream biota, Theoretical analysis.

Views of aquatic scientists who gathered to assess the ability of stream ecosystem theory to predict recovery from disturbance are summarized. Two views of disturbance were evident: a discrete removal of organisms versus an unusual deviation from normal. These were perceived as applying to different scales and/or objectives. Long-term information is required from both points of view to define recovery. Recovery has both spatial and temporal components, and includes both physical and biological processes. Consensus was very strong that a major role for theory lies in the understanding of spatial aspects, temporal scales, coupling of physics and biology, and the interaction of these features in recovery processes. Some progress is evident, but among the topics identified as critical were: homo-versus heterogeneous distribution of disturbance, local extent of disturbance relative to regional context, critical vs. noncritical patches (size and location) of disturbance at different spatial scales and temporal frequencies, delineation of reversible and nonreversible processes, and physical and biological constraints on the time frame for recovery. Such concepts need attention across different types of lotic ecosystems. There was a strong consensus that a national monitoring system of representative lotic ecosystems within ecological regions be established. The purpose of this monitoring system would be to acquire long-term data on natural variability, to establish viable indicators of spatial and temporal aspects of recovery, and to develop and test emerging theoretical developments. In three cores from an acidic lake in the Adirondack State Park of New York, iron cycling accounted for diagenetic enrichment of up to 14% of sediment dry mass. The accuracy of the sediment accumulation rates calculated from the constant rate of supply (CRS) model and the dating and sediment accumulation rates calculated from the constant initial concentration (CIC) lead-210 models were affected by post-depositional movement of iron about the sediment-water interface and through the sediment. Dating biases from iron diagenesis reached as high as 57% and biases to calculated sediment accumulation rates ranged up to approximately 15%. The difference between the iron-corrected and uncorrected dating was not much greater than the error expected from routine analytical precision. However, under circumstances of low sediment accumulation rates and high iron enrichment, significant deviations in dating and sediment accumulation calculations for both CRS and CIC lead-210 models may become noteworthy. The accuracy of any sediment dating technique, normalized to dry sediment mass, should be carefully evaluated in low sedimentation rate environments which show evidence of post-depositional movement of iron or other diagenetically active materials. Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 65-73, May 1990. 6 fig, 2 tab, 7 ref. International Atomic Energy Agency Grant No. 4621/EP.

Descriptors: *Coagulation, *Coastal waters, *Particle size, *Sediment concentration, *Suspended solids, Accumulation, Diffusion, Estuaries, Flocculation, Greece, Patras, Sedimentation.

The granulometry of the suspended matter in various coastal waters collected around Patras, Greece, together with the average particle diameters, have been determined during a twelve month period by a simple, quick, inexpensive and relatively accurate photosedimentometer. The particle size distributions were found to be self-preserving and independent of time, hydrologic regime, nature and amount of particulate materials and particle mobility. The experimental results show that Brownian diffusion is the dominant factor in flocculation processes in coastal waters. The flocculation processes of the suspended particles taking place when river meets sea water occur because of the increase of ionic strength during mixing. As a consequence, intensive sedimentation and accumulation of this material can occur generally in somewhat restricted zones in an estuary. (Brunone-PTT)

Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 1092-1095, July/August 1990. 2 fig, 1 tab, 27 ref.

Descriptors: *Erosion, *Erosion control, *Infiltration rate, *Rainfall impact, *Rainfall infiltration, *Soil amendments, *Soil erosion, *Soil water, Fluid drops, Particulate matter, Polymers, Simulated rainfall, Soil aggregates, Surface sealing.

The effects of nonionic, anionic and two charge densities of cationic derivatized guar products on erosion and infiltration rates were investigated. The polymers were mixed with distilled water at concentrations from 0 to 20 g/cu m and applied through a rainfall simulator in the laboratory. Untreated distilled water was applied to an Arlington sandy loam soil (Haplic Durixeralf) with the soil surface both unprotected and protected by a fiberglass sheet placed 0.5 cm above the soil surface. All polymer treatments were applied to the unprotected soil surface. Distilled water drop impact greatly reduced infiltration rate and increased erosion, compared with no impact. The anionic and nonionic polymers did not significantly affect erosion or infiltration rate, compared with distilled water. The cationic polymers significantly increased infiltration rate and erosion. The higher charge cationic polymer produced significantly higher values than the lower charge polymer at the same concentration. The distilled water treatment with impact caused severe aggregate disruption and dispersion, producing a layer of fine material at the surface that decreased infiltration rate. Apparently, the very fine particulates became imbedded in the soil matrix, which made them less susceptible to lateral transfer with flowing water. The flocculating action of the cationic polymer created larger particulates, which had very little effect in reducing infiltration rate but were more susceptible to erosion. Under the conditions of the experiment, particulates between 0.05 and 0.25 mm were most susceptible to transport by a thin sheet of flowing water. (Author's abstract)

HALITE DEPOSITIONAL FACIES IN A SOLAR SALT POND: A KEY TO INTERPRETING PHYSICAL ENERGY AND WATER DEPTH IN ANCIENT DEPOSITS.
ARCO Oil and Gas Co., Plano, TX.
C. R. Handford.
Geology GLGYBA, Vol. 18, No. 8, p 691-694, August 1990. 7 fig, 17 ref.

Descriptors: *Brines, *Chemical precipitation, *Crystallization, *Deposition, *Geologic history, *Halite, *Sedimentary structures, Aragonite, Evaporation ponds, Gypsum, Saline water, Salt pans, Salts, Sedimentary rocks.

Subaqueous deposits of aragonite, gypsum, and halite are accumulating in shallow solar salt ponds constructed in the Pekelmeer, a sea-level salina on Bonaire, Netherlands Antilles. Several halite facies are deposited in the crystallizer ponds in response to differences in water depth and wave energy. Cumulate halite, which originates as floating rafts, is present only along the protected, upwind margins of ponds where low-energy conditions foster their formation and preservation. Cornet crystals with peculiar mushroom and mortarboard shaped caps precipitate in centimeter deep brine sheets within a couple of meters of the upwind or low-energy margins. Downwind from these margins, cornet and chevron halite precipitate on the pond floors in water depths ranging from a few centimeters to approximately 60 cm. Halite pisoids with radial-concentric structure are precipitated in the swash zone along downwind high-energy shorelines where they form pebbly beaches. This study suggests that primary halite facies are energy and/or depth dependent and that some primary features, if preserved in ancient halite deposits, can be used to infer physical energy conditions, subenvironments such as low to high-energy shorelines, and extremely shallow water depths in ancient evaporite basins. ESTIMATING EROSION RISK ON FOREST LANDS USING IMPROVED METHODS OF DISCRIMINANT ANALYSIS.
Pacific Southwest Forest and Range Experiment Station, Arcata, CA.
J. Lewis, and R. M. Rice.
Water Resources Research WRERAQ, Vol. 26, No. 8, p 1721-1733, August 1990. 2 fig, 6 tab, 37 fig, append.

Descriptors: *Discriminant analysis, *Erosion, *Forest soils, *Forest watersheds, *Land use, *Logging, *Risk assessment, *Soil erosion, Estimating equations, Forest hydrology, Model studies, Statistical analysis.

Excess erosion from logging and forest roads has long been of concern to forest managers and the general public. Studies in California concluded that the key to reducing erosion from logged areas was to identify critical sites yielding at least 189 cu m/ha; this led to a definition of a critical site as any 0.81 ha acre area enclosing more than 153 cu m of erosional voids. A population of 638 timber harvest areas in northwestern California was sampled for data related to the occurrence of critical amounts of erosion. Separate analyses were done for forest roads and logged areas. Linear discriminant functions were computed in each analysis to contrast site conditions at critical plots with randomly selected controls. Bootstrapping was used extensively in the development and testing of the equations, in estimating prediction bias, and in placing confidence limits around parameters and posterior probabilities. The resulting three-variable equations had classification accuracy, corrected for prediction bias, of 77.7% for road plots and 69.2% for logged area plots. The variables appear to be expressing three important site conditions related to erosion risk: (1) instability-promoting effects of gravity (slope steepness), (2) the convergence of subsurface water, and (3) strength of materials (parent rock strength). The use of linear discriminant functions facilitates the explicit consideration of erosion risk when planning land-disturbing activities. None of the steps required for the utilization of the equations are particularly difficult, but they do require a more rigorous approach to erosion risk analysis. (Tappert-PTT)

FAN-DELTA AND BRAID-DELTA SYSTEMS IN PENNSYLVANIAN SANDIA FORMATION, TAOS TROUGH, NORTHERN NEW MEXICO: DEPOSITIONAL AND TECTONIC IMPLICATIONS.
Texas Univ. at Dallas, Richardson. Inst. for Geosciences.
K. Soegaard.
Geological Society of America Bulletin BUGMAF, Vol. 102, No. 10, p 1325-1343, October 1990. 14 fig, 2 tab, 79 ref.

Descriptors: *Alluvial channels, *Channel morphology, *Deltas, *Geology, *Geomorphology, *Paleohydrology, *Sedimentary basins, *Tectonics, Alluvial deposits, Alluvial fans, New Mexico, Pennsylvanian Sandia Formation, Sandstones, Sedimentation rates, Taos Trough.

Fan-delta and braid-delta deposits were distinguished in the Pennsylvanian Sandia Formation, Taos Trough, New Mexico. Fan deltas were deposited in close proximity to the active western boundary fault of the Taos Trough and occur as coarse-grained aggradational sequences. Alluvial processes in fan-delta complexes were characterized by unrestricted sheetflood and ephemeral stream flow deposition. Subaqueously deposited, fan-delta conglomerates and sandstones arranged in lenticular units encased by basinal mudstones were emplaced by a variety of high density and dilute gravity flow processes. Braid-delta complexes were characterized by channelized alluvial deposition in which discharge was variable, but perennial. Perennial discharge in the braid deltas was in response to expansion of the drainage area in the Taos Trough hinterland through time. This resulted in increased sediment discharge into the trough and enabled basinward extension of the alluvial plain by braid-delta progradation. It is concluded that fan deltas are associated with steep basin margins in which overall subsidence rates exceed sedimentation rates. Braid deltas are related to low gradient basin margins along which sedimentation rates are greater than subsidence rates. Distribution of fan-delta and braid-delta complexes in the Sandia Formation is dictated by tectonic load-induced subsidence in the Taos Trough and may be used as a guide for resolving evolutionary history of other types of active sedimentary basins. In June 1987, Carroll Glacier (Glacier Bay, southeast Alaska) began to surge southeastward toward Wachusett Inlet. Between 9 June and 1 July 1987, the terminus advanced with a mean velocity of 29 m/day, slowing afterward but attaining a net displacement of >1 km by July 1988. A proglacial lake lay directly in the path of the surge and became partly overridden, with only 25% of its former basin remaining exposed after 1 yr. The effects of the ice advance on the lake were profound. Early in the surge, lake water samples attained suspended sediment concentrations exceeding 9 g/L well above bottom. Extremely rapid sedimentation, locally attaining 8 m in 36 days, produced nearly uniform depths of 8-9.5 m by August 1987. Sediment deposited during the surge was extremely soft and underconsolidated, composed of massive to irregularly layered muddy silt produced by disruptions of the lake floor and by remobilization of lake bottom sediment by sediment gravity flows. A prominent push moraine, developed from a low ridge initiated by glacial loading, formed where the glacier overrode sandy substrate, but no similar feature was observed in the muddy lake floor. By July 1988, the surge had greatly diminished, and the remaining lake basin was slowly uplifted by displacement from the weight of the ice. By the end of August 1988, most of the lake floor was completely exposed and undergoing erosion by meltwater channels, causing abnormally high suspended sediment loads at the outlet compared to the previous year when the lake was an effective sediment sink. CONTROLLING MECHANISM OF LOCAL SCOURING.
Royal Inst. of Tech., Stockholm (Sweden). Dept. of Hydraulics Engineering.
B. Dargahi.
Journal of Hydraulic Engineering (ASCE) JHEND8, Vol. 116, No. 10, p 1197-1214, October 1990. 11 fig, 14 ref.

Descriptors: *Channel erosion, *Erosion, *Flow around objects, *Scour, *Sediment transport, *Vortices, Boundary layers, Clear water, Flow, Mathematical analysis, Mathematical equations, Turbulent flow.

Experimental study of clear water scouring around a circular cylinder showed that the scour mechanism is coupled to the three-dimensional separation of the upstream boundary layer and the periodic vortex shedding in the wake of the cylinder. The first scour appears in the wake of the cylinder. The main scouring in the upstream region is a system of horseshoe vortices. The vortices have a periodical character that causes a triple-scour effect to develop in the upstream region. During scouring, the number and periods of horseshoe vortex shedding undergo no appreciable change. Despite the clear water stage, the transport phenomenon is periodical. Transport of sediment takes place through turbulent scales of comparable size to macro-length scales. The size of the horseshoe vortices is representative for the macroscale. Wake scouring is caused by the primary wake vortices and the accelerated side flow. The process is characterized by a strong periodical transport and the formation of ripples. The periodicity is controlled by the shedding frequency of the wake vortices. Collars attached to the cylinder cannot prevent the formation of the vortices. (Author's abstract)

FIELD VERIFICATION OF 2-D AND 3-D SUSPENDED-SEDIMENT MODELS.
Waterloopkundig Lab. te Delft (Netherlands).
L. C. van Rijn, H. van Rossum, and P. Termes.
Journal of Hydraulic Engineering (ASCE) JHEND8, Vol. 116, No. 10, p 1270-1288, October 1990. 11 fig, 1 tab, 13 ref, append.

Descriptors: *Model studies, *Model testing, *Sediment concentration, *Sediment transport, *Suspended sediments, Eastern Scheldt Estuary, Estuarine sediments, Flow velocity, The Netherlands, Unsteady flow.

A tidal channel in the Eastern Scheldt estuary in the Netherlands was closed by pumping a sand-water mixture into the closure gap. During the closure, field measurements of flow velocities and sand concentrations were carried out. Based on the results of the field measurements, computations with two-dimensional and three-dimensional sediment transport models were performed. The two-dimensional computations showed that the depth-integrated transport rates could be reasonably predicted (within a factor of 2) in case of diverging flow. However, less satisfactory results were obtained for converging flow. The three-dimensional computations showed quite good agreement between measured and predicted flow velocities, sediment concentrations, and transport rates, both for flood and ebb flow. A sensitivity analysis with respect to the time-dependent concentration term, the shape of the velocity profiles, the turbulent mixing coefficients, and the bed material gradation indicated no significant influence of these parameters. The main reason for the difference between measured and predicted results was caused by the formula modeling the sediment pickup rate (at the bottom). (Author's abstract)

GEOSTATIC COMPACTION BEHAVIOUR OF KAOLIN MUDS--EFFECTS OF DIFFERENT SAMPLE PREPARATION PROCEDURES.
Kiel Univ. (Germany, F.R.). Geologisch-Palaeontologisches Inst. und Museum.
V. Feeser, and H. Knoke.
Applied Clay Science ACLSER, Vol. 5, No. 1, p 67-83, May 1990. 8 fig, 3 tab, 18 ref.

Descriptors: *Clays, *Consolidation sedimentation, *Laboratory methods, *Sample preparation, *Sedimentology, *Soil compaction, *Soil mechanics, Boundary conditions, Fabrics, Mud-water interfaces, Slurries.

Experimental laboratory studies of initial compaction mechanisms in clay muds may be performed either by artificially sedimented samples or by simple stirred pastes (without consideration as to application of the results for natural processes). Little intensive research has been performed on the differences in the two preparation procedures. Homogeneous kaolin was geostatically consolidated in the laboratory. Samples were prepared by mixture of a clay-water slurry and sedimentation with clay-water suspension. The stress-strain behavior was analyzed by rigid analytical and experimental boundary conditions. It was found that the method of sample preparation does not qualitatively affect the initial compaction behavior of clay muds. The correlations between compression and swelling parameters indicate that all the samples, regardless of the method of preparation and the resulting differences in fabric, show no significant differences in plastic potential. Less deformation work needs to be performed to consolidate sedimented samples than is the case with stirred samples. With regard to reproducibility, significance, and application of correlations between physicochemical and mechanical behavior, normal soil mechanical standards are not sufficient to reveal all the mechanisms of clay mud compaction. Stirred samples can be used for basic research in studies of material laws without affecting qualitatively the degree of prediction. Sedimented samples adapted to the respective environment must be employed if a direct application to natural conditions is desired. These results are in contrast to previous findings. (Fish-IT)

Descriptors: *Infiltration, *Rainfall-runoff relationships, *Soil erosion, *Soil properties, *Soil surfaces, *Topsoil, Hydraulic conductivity, Hydrologic models, Model studies, Morphology, Overland flow, Runoff coefficient, Runoff volume, Saturated soils, Surface sealing.

Rainfall experiments have been conducted in the laboratory in order to assess the hydrological response of topsoils very susceptible to surface sealing and containing rock fragments in different positions with respect to the soil surface. For a given cover level, rock fragment position in the topsoil has an ambivalent effect on water intake and runoff generation. Compared to a bare soil surface rock fragments increase water intake rates as well as time of runoff concentration and decrease runoff volume if they rest on the soil surface. For the same cover level, rock fragments reduce infiltration rate and enhance runoff generation if they are well-embedded in the top layer. The effects of rock fragment position on infiltration rate and runoff generation are proportional to cover percentage. Micromorphological analysis and measurements of the saturated hydraulic conductivity of bare topsoils and of the top layer underneath rock fragments resting on the soil surface reveal significant differences; runoff generated as rock flow or as Horton overland flow can (partly) infiltrate into the unsealed soil surface under the rock fragments, provided that they are not completely embedded in the top layer. Hence, rock fragment position, beside other rock fragment properties, should be taken into account when assessing the hydrological response of soils susceptible to surface sealing and containing rock fragments in their surface layers. A simple model, based on the proportions of bare soil surface, soil surface occupied by embedded rock fragments, and soil surface covered with rock fragments resting on the soil surface, describes the runoff coefficient data relatively well. NOURISHMENT OF PERCHED SAND DUNES AND THE ISSUE OF EROSION CONTROL IN THE GREAT LAKES.
Michigan Univ.-Flint. Dept. of Resource Science.
W. M. Marsh.
Environmental Geology and Water Sciences EGWSEI, Vol. 16, No. 2, p 155-164, 1990. 6 fig, 1 tab, 24 ref.

Descriptors: *Dunes, *Erosion control, *Great Lakes, *Lake shores, *Wind erosion, Aeolian deposits, Lake management, Sand, Vegetation effects, Water level fluctuations.

Although limited in coverage, perched sand dunes situated on high coastal bluffs are considered the most prized of Great Lakes dunes. Grand Sable Dunes on Lake Superior and Sleeping Bear Dunes on Lake Michigan are featured attractions of national lakeshores under National Park Service management. The source of sand for perched dunes is the high bluff along their lakeward edge. As onshore wind crosses the bluff, flow is accelerated upslope, resulting in greatly elevated levels of wind stress over the slope brow. On barren, sandy bluffs, wind erosion is concentrated in the brow zone, and for the Grand Sable Bluff, it averaged 1 cu m/yr per linear meter along the highest sections for the period 1973-1983. This mechanism accounts for about 6,500 cu m of sand nourishment to the dunefield annually and clearly has been the predominant mechanism for the long-term development of the dunefield. However, wind erosion and dune nourishment are possible only where the bluff is denuded of plant cover by mass movements and related processes induced by wave erosion. In the Great Lakes, wave erosion and bluff retreat vary with lake levels; the nourishment of perched dunes is favored by high levels. Lake levels have been relatively high for the past 50 years, and shore erosion has become a major environmental issue leading property owners and politicians to support lake-level regulation. Trimming high water levels could reduce geomorphic activity on high bluffs and affect dune nourishment rates. Locally, nourishment also may be influenced by sediment accumulation associated with harbor protection facilities and by planting programs aimed at stabilizing dunes. (Author's abstract)

Organic matter from living algal mats and their decay products from mud pools of the geothermal areas at Rotokawa and Waimangu, New Zealand, was separated into solvent-extractable and protokerogen fraction. Fourteen elements were determined in the bulk samples and the solvent extractable fractions by optical emission spectroscopy, and 15 elements (including some rare earth elements) in the protokerogen concentrates by instrumental neutron activation analysis. Many elements were strongly enriched in the organic fractions as compared to the bulk sample: concentrations in the extracts are of the order of grams per kg for P, Zn and Sb, and 10g/kg for As; those in protokerogens are 10 g/kg for Fe and Sb, and 100 mg/kg for La and Ce. The results demonstrate that in contact with metal-rich geothermal waters, biogenic material is able to incorporate high amounts of metals into the organic matrix. While inorganic contributions to the solvent-extractable fractions are shown to be minimal, the presence of inorganic microinclusions in protokerogen concentrates cannot be excluded. pretation, Land management, Rills, Sheet erosion, Soil management.

Progress in erosion research has been substantially restrained because there is no simple technique for the estimation of long-term soil loss rates. A technique has been developed that uses a calibration between measured soil loss from small plots with measured soil CS-137 content (expressed as a percentage loss relative to the Cs-137 content of a local stable reference soil). Sites of soil loss measurement throughout Australia were sampled by coring to determine their relative Cs-137 content. Measurements made on erosion/runoff plots are confined to the effects of shallow, ephemeral rills and sheet erosion by water. Plotting the average soil loss results against residual cesium content relative to a local, stable reference site indicated that their relationship was exponential. Soil loss data were therefore log-transformed and a regular regression analysis was performed on the data. Precision was considerably improved by partitioning the data into sets for cultivated soils and pasture land. These regressions were highly significant for pasture plot results and for cultivated sites. The measured soil losses form erosion/runoff plots are real data which may be extrapolated to other areas if an acceptable correlation is found with an easily measured soil attribute. The 95% confidence limits on the regressions reflect real field variability. Comparisons of prediction of soil erosion by the regression method and by the proportional method indicate that estimates by the proportional method are approximately 10 times greater. The regression represents a simple and rapid tool for the estimation of net soil loss from sites which have a uniform and continuous history of land-use. (Fish-PTT)

Journal of Hydraulic Engineering (ASCE) JHEND8, Vol. 116, No. 11, p 1416-1421, November 1990. 1 fig, 1 tab, 6 ref, append.

Descriptors: *Alluvial channels, *River mechanics, *Sediment transport, *Shear stress, *Turbulent flow, Fall velocity, Open-channel flow, Particle size, Sediment discharge, Sedimentation rates, Settling velocity.

Current knowledge of the mechanics of alluvial channels depends very largely on calculations of turbulent shear stress; typical examples are the beginning of motion of sediment particles and sediment transport in alluvial channels. Comparatively little is known about shear stresses in sediment-laden flows. The analysis of turbulent shear stress for steady-uniform flows carrying heterogeneous sediment mixtures provides additional insight on the role played by sediment size gradation and fall velocity by size fraction. A derivation has been developed of turbulent stress in heterogeneous sediment-laden flows, and considers the steady and uniform motion of this flow type in an open channel. These relationships demonstrate that the average velocity in the vertical direction is not zero but proportional to the fall velocity of sediment particles and the concentration of each size fraction. The derivation shows that turbulent shear stress in sediment-laden flows is similar to that of the water flow except that the fluid mass density is replaced with the density of the water sediment mixture. It was concluded that the sediment size distribution and the fall velocity of sediment particles do not affect turbulent shear stress of heterogeneous sediment mixtures under steady-uniform flow conditions. FLUME EXPERIMENTS ON THE TRANSPORT OF HEAVY MINERALS IN GRAVEL-BED STREAMS.
Massachusetts Inst. of Tech., Cambridge. Dept. of Earth and Planetary Sciences.
R. A. Kuhnle, and J. B. Southard.
Journal of Sedimentary Petrology JSEPAK, Vol. 60, No. 5, p 687-696, September 1990. 9 fig, 2 tab, 40 ref. Anglovaal Mining Company, the MIT Department of Earth, Atmospheric, and Planetary Sciences, and the National Science Foundation Grant EAR 84-15466.

Descriptors: *Flow models, *Flumes, *Hydraulic models, *Minerals, *Sediment transport, Channel flow, Degradation, Erosion, Gravel, Sedimentation, Slopes, Stream discharge, Streamflow data.

Heavy-mineral transport and deposition by shallow unidirectional flows in a gravel-bed channel were studied in a water-recirculating sediment-feed flume. The heavy minerals became concentrated into a thin layer (the heavy infralayer) composed of nearly 100% heavy minerals lying beneath a thin surficial layer of low-density sediment (the light supralayer). Heavy minerals were not transported past a given location on the bed until the heavy infralayer was fully developed there. Heavy minerals were transported on the upper surface of the heavy infralayer only when local and temporary erosion of the light supralayer exposed the heavy infralayer. In two runs, one with sediment feed and one without, overall degradation of the bed was forced by slow lowering of a tailgate at the downstream end of the channel. In the sediment-feed run a downstream-prograding heavy infralayer formed as in the nondegrading runs. In the run without feed, the surficial heavy-mineral concentration increased gradually at all points along the channel to the end of the run. These results indicate that ultimately the surficial heavy-mineral concentration would reach a steady state and the bed slope would change until the flow can transport all of the heavy-mineral sediment supplied by local exhumation. A too-small initial slope caused overall bed aggradation in the early parts of two runs. Heavy minerals in the feed sediment were transported only a short distance downstream to form a zone of higher but downstream-decreasing heavy mineral concentration extending vertically through the deposit. It is hypothesized that the downstream length of this zone would increase as the heavy-mineral feed rate increases relative to the bed aggradation rate. (Author's abstract)

GLACIOMARINE SEDIMENTATION IN DISRAELI FJIORD, HIGH ARCTIC CANADA.
Alberta Univ., Edmonton. Dept. of Geography.
D. S. Lemmen.
Marine Geology MAGEA6, Vol. 94, No. 1/2, p 9-22, July 1990. 8 fig, 1 tab, 69 ref. Natural Sciences and Engineering Research Council of Canada grant A6680; Boreal Institute for Northern Studies, University of Alberta grant.

Descriptors: *Arctic zone, *Canada, *Fjords, *Glacial sediments, *Glaciohydrology, *Glaciology, *Sediment transport, *Sedimentation, Climatic changes, Deposition, Ellesmere Island, Geologic history, Glacial drift, Glaciation, Glaciers, Holocene Epoch, Sea ice, Sedimentation rates, Settling velocity, Snowmelt.

Disraeli Fjiord, in High Arctic Canada, represents a glaciomarine environment unique to the north coast of Ellesmere Island, featuring floating glacier tongues, multi-year landfast sea ice and a strongly stratified water body which results from enclosure of the fiord by Ward Hunt Ice Shelf. It is a very low energy depositional environment, even at sites proximal to glaciers. Sediment enters the fiord by interflow and is deposited through suspension settling. Ice rafting is precluded by the year-round sea ice cover. Sedimentation rates in the inner fiord since about 7000 years B.P. are estimated to be 5-10 cm/ka, a reflection of the limited sediment influx from cold-based glaciers which contact the fiord. Changes in sediment structure through the Holocene reflect changes in the rate and process of sediment input as well as changes in fiord circulation, all of which relate to regional climate. During deglaciation (early Holocene) sedimentation rates were orders of magnitude greater than at present. Subglacial meltwater was the dominant source of inflow, with sediment transported in turbid plumes as overflow or interflow and deposited through suspension settling. This is supportive of other studies indicating that a pronounced climatic amelioration led to warm-based glaciers at this time. (Author's abstract)

An optimal test system for the use of the acetylene reduction technique to determine the nitrogenase activity and the calculation of atmospheric nitrogen input to stagnant water bodies requires rapid measurements over a small range of substrate concentrations, especially in the case of a narrow vapor-aqueous phase relation. An equation is presented for the calculation of real optimal acetylene concentrations in the aqueous phase at different aqueous-vapor phase relations and variable injection volumes. Comparison of the acetylene reduction with the real dinitrogen fixation showed that the commonly assumed conversion factor of 3 is untenable. In the course of a simulated light-dark cycle a substantial dark acetylene reduction was observed. Relatively high rates were measurable immediately after the beginning of the light period. This discrepancy of acetylene and dinitrogen reduction rates can be explained in the context of the hydrogenase function of nitrogenase. Steady state uptake kinetics show that with substrate-saturated N2 assimilation one mole of H2 is produced per mole of fixed N2. Therefore the assumed theoretical factor must not be lower than 4. The relatively high conversion factors could be explained by using acetylene as substrate; the whole electron flow capacity of the nitrogenase complex is used. Under this condition H2 production may be completely inhibited. Therefore a considerable overestimation of the dinitrogen input calculated from acetylene reduction rates occurs if a conversion factor is used without regarding its light dependence. RELATIONSHIP BETWEEN MIXING PROCESS AND CONCENTRATIONS OF MAJOR IONS IN SPANISH MEDITERRANEAN BRACKISH WATERS.
Barcelona Univ. (Spain). Dept. de Ecologia.
P. Lopez.
Archiv fuer Hydrobiologie AHYBA4, Vol. 119, No. 2, p 231-241, 1990. 3 fig, 3 tab, 28 ref.

Descriptors: *Brackish water, *Coastal waters, *Saline-freshwater interfaces, *Water chemistry, Calcium, Carbonates, Chlorides, Gypsum, Ions, Magnesium, Mediterranean Sea, Potassium, Seas, Sodium, Sulfates.

The chemical composition of 17 coastal systems located in the Mediterranean Spanish basin was studied in order to identify the main processes controlling the concentrations of major ions (HCO3(-), Cl(-), SO4(2-), Ca(2+), Mg(2+), Na(+), K(+)) in the brackish waters of the region. Theoretical concentrations of ions were calculated assuming a single mixing process between seawater and mineralized freshwaters. In the El Hondo area, seawater and freshwater inputs entered the lagoons partially by underground inflow, leaching areas with gypsum deposits. Both sea and freshwaters were undersaturated with respect to gypsum, so redissolution took place, increasing the concentrations of Ca(2+) and SO2(2-). A good correlation between percentage of seawater and concentrations of Na(+), SO2(2-) and Mg(2+) was found at El Hondo. Ca(2+) concentration was more independent of seawater and the mixing process due to the participation of Ca(2+) in chemical precesses. On the Valencia coast, the systems studied always received a very low percentage of seawater, so this parameter was not correlated to observed ionic concentrations. Highly significant coefficients found between observed and predicted values for Na(+), SO2(2-) and Mg(2+) would be due to freshwater influence. As in El Hondo area, reaction between seawater and fluvial clays involved a decrease of K(+) concentration, which in this area was not compensated by marine contribution. In the Castellon region, there were no perennial rivers entering the lagoons and inflow was by groundwater upwelling, seawater filtration through sand barriers and ephemeral runoff. The substrate was mainly calcareous, so redissolution of calcite took place causing an increase in HCO3(-) and Ca(2+) inputs. In the regions studied, Na(+) was the only ion that could be considered dependent on the proportion of seawater alone. SO4(2-), Mg(2+), and K(+) were also greatly influenced by marine inputs, but their concentrations were modified by geological, hydrological and biological factors. (Mertz-PTT)

Descriptors: *Acid rain, *Artificial recharge, *Geochemistry, *Path of pollutants, *Stable isotopes, *Water chemistry, Germany, *Surface-groundwater relations, Springs, Karst hydrology, Sulfur radioisotopes, Oder River, Basin of Pohlde, Rhume River, Harz Mountains.

An investigation was conducted during a dry period of weather in August 1988, the influence of artificially high water at the Oder River on the hydrochemical and isotopic composition of karstwaters from the 'Basin of Pohlde', and the springs of the Rhume River. For the first time, the separate effects of the infiltrating Oder River water on the discharge and hydrochemical composition of the springs were clearly demonstrated. In response to the high water, the well water BL5 showed a complex subsurface mixing behavior. The delta S-34 values of the dissolved sulfate indicated 18 to 36 mg/L of anthropogenic sulfate. Southernmost Norway is one of the areas of the industrialized world where many of the streams and lakes are most acid, even though the air and the rainfall is among the least polluted. Chemical composition of stream and lake water depend upon complicated biogeochemical ion exchanges and weathering reactions between precipitation water and permeable material in the catchments. An examination of streams in southern Norway reveals that acid streams are mainly found in areas with sparse mineral soil and acid raw humus (mor) top soils. Changes in vegetation may change mull to mor and vice versa. In addition, three lakes in areas with acid precipitation and mor top soil in southern Norway were investigated. Two of them had acid after 1950 and had also acid periods in pre-industrial time following vegetation changes similar to the changes in the twentieth Century. The third lake in a catchment with thick mineral subsoils was never acidified. (Author's abstract)

Input-output budgets are presented for three granitic catchments, with contrasting vegetation types (Spruce, Beech, and grasslands), for the Mont Lozere region of France. Budget results are compared with information for analogous catchments with varying atmospheric pollution loading. Comparisons show relatively small losses of cations and marked sulfate retention in the soils (particularly for the beech and grassland sites) of the Mont Lozere catchments. Retention of sulfate may be underestimated, particularly for the spruce site, owing to occult and dry deposition inputs which have not been measured. Losses of the base cations are least significant for the beech forest, and this is linked to low bicarbonate production coupled with high sulfate retention in the soil. The spruce afforestation programme has led to a marked cation-loss increase although the streams have yet to acidify. Deforestation leads to further cation losses in relation to increased nitrate leaching. The biogeochemical functioning of the Mont Lozere ecosystems, although slightly disturbed, is not in steady state; sulfate is still accumulating and the effects of afforestation and harvesting are marked. Bulk precipitation, throughfall, soil solution at 20 and 40 cm depths, and stream water were monitored for 2-4 years in a holm-oak forest on schists in the Montseny Mountains (NE Spain). Bulk precipitation was mildly acidic, with Ca(2+) and SO4(2-) as dominant ions. Canopy interactions produced a throughfall less acidic than bulk precipitation and enriched in all other ions. Large amounts of K(+) were leached from the canopy. It is believed that leaching makes a major contribution to Mg (2+) enrichment beneath the canopy. Sulfate was the dominant mobile anion in the soil water, being largely accompanied by Ca(2+). Potassium and NO3(-) were depleted within the soil water with respect to throughfall, probably owing to biological uptake and cation exchange, and incorporation of K (+) into clay lattices. Subsurface flow dominated the hydrology of the small forested catchment studied. Stream water was basic and rich in bicarbonate. Its chemistry revealed fast rates of weathering of sodium-, and magnesium-bearing silicates (mainly albite and chlorite, respectively). Soil respiration and silicate hydrolysis resulted in HCO3(-) being the dominant mobile anion in stream water. Calcium to chloride ratios were similar in bulk precipitation and in stream water, indicating that Ca (2+) release from weathering has been counteracted by plant uptake. Nutrient uptake by this aggrading forest strongly influences the solution dynamics of K (+), NO3 (-), and Ca (2+). It is concluded that: (1) this forest does not currently receive acidic atmospheric deposition, (2) the neutralization capacity of the soil-bedrock system is quite high, (3) biotic regulation and silicate weathering are the major processes shaping the solution biogeochemistry in this Mediterranean forest ecosystem. The hydrochemistry of a small upland catchment during a summer storm, following six weeks of low flow, is described. The storm exhibited several unusual features which may be attributed to the dry antecedent conditions. Streamwater concentrations of all ions analyzed increased during the event but the timing of the increases varied according to the initiation of flows controlling the supply of particular ions. The increase in the concentration of calcium in the stream coincided with onset of overland flow, and appears to result from flushing of accumulated weathering products from a narrow strip of mire which provides a major pathway for storm water in the catchment. Natural soil pipes appear to be the main source of the increase in streamwater concentrations of both organically and inorganically complexed aluminum. Concentrations of inorganic aluminum in pipe water were considerably greater than those observed during previous events, possibly another result of the long period without flow. During the stream recession inorganic aluminum remained high, reflecting contribution from aluminum-rich throughflow. It is concluded that the chemistry of the stream at a given time is controlled by the relative importance of contributing sources of water which is, in turn, controlled by hydrological factors such as antecedent conditions and rainfall intensity and duration. chemical technique is used to provide hydraph separation for streams in the Llyn Brianne ea of Mid-Wales. Hydrograph separation can be ployed to determine the relative proportions of ch component and the changes in the relative portions of components, which occur during a rm event. These short-term responses can be mbined with the output from long-term models enable a more comprehensive assessment of sitivities to acidification. The chemical techque uses mixing relationships for a conservative mponent, the acid neutralization capacity NC). A relationship is established between pH d ANC using the chemical analyses for spot mples and with this the ANC is calculated from ntinuous pH measurements. The technique sepaes the hydrograph into soil waters and deeper ters. A comparison of the effects of land-use ferences is made. The results suggest that nges in both soil chemistry and hydrological hways may result from afforestation. Long-term modeling work may benefit form a combined approach in which mixing-model results are used to allow predictions of short-term stream chemistry changes. (Author's abstract)

Stream chemistry data from the Allt a'Mharcaidh catchment (10 sq km) in Scotland have been the subject of an analysis in which conservative mixing of two sources of constant concentration is assumed for individual chemical species. The mixing analysis has been carried out for alkalinity, silica, calcium, magnesium, sodium, chloride, and total organic carbon (TOC). The analysis shows a consistent behavior of alkalinity and TOC, but other species have an apparently contrasting response. The implications are that event response is due primarily to low alkalinity, high TOC water (associated with soil water) and that baseflow is from an unidentified high alkalinity source. However, displacement of alkaline-rich water is apparent during larger events. Other species show contrasting response, possibly as a result of spatial heterogeneity. Despite the fact that many questions remain unanswered, this mixing analysis is a powerful tool for examining the data and can produce hypotheses for more detailed examination. (Author's abstract)

New hydrochemical information is available on soil waters for the Birkenes catchment in southern Norway. This information is in disagreement with the existing Birkenes model: the two reservoirs of the model cannot easily be identified with particular areas or soil horizons in the catchment. Here, a new model is presented allowing such an identification while still representing a simple, lumped structure. The simulated flow patterns in the model are evaluated through a three-step procedure involving: (1) reproduction of the hydrograph, (2) reproduction of the chemically inert (18)O isotope in runoff, and (3) simulation of H(+), Al(i) (inorganic monomeric aluminum), and Ca in runoff by mixing of measured soil water end member compositions attributed to each model reservoir. The first two tests are met reasonably well within the proposed structure, whereas the third requirement, if indeed the measured end-member compositions are representative for the catchment, implies structural changes in the way the Birkenes model describes water routing. More field work is required on soil water chemistry, for instance in the deeper layers in the valley bottom, before a further iteration in model development can be undertaken. (Author's abstract)

SEASONAL CHANGES IN IRON TRANSPORT AND NATURE OF DISSOLVED ORGANIC MATTER IN A HUMIC RIVER IN NORTHERN FINLAND.
Oulu Univ. (Finland). Dept. of Botany.
K. Heikkinen.
Earth Surface Processes and Landforms ESPLDB, Vol. 15, No. 7, p 583-596, November 1990. 3 fig, 6 tab, 60 ref.

Descriptors: *Dissolved organic carbon, *Dissolved solids, *Finland, *Iron, *Organic matter, *River flow, Color, Flooding, Fluorescence, Humic substances, Seasonal variation, Stream discharge.

Seasonal changes in the nature of dissolved organic matter have been reported in streams and organically colored rivers in the boreal region. These changes influence the biology of flowing water in many ways, but are still poorly known and understood. Changes in the concentration of iron and dissolved organic matter (DOM), and in the color and fluorescence properties in the River Liiminkkijoki in northern Finland were investigated as functions of the seasonal flow regime over a two-year period. The iron concentration in filtrates and the ratio of iron to dissolved organic carbon (DOC) in the river increased under low flow conditions and decreased during the flood periods. The color of the dissolved organic matter increased with increasing iron content, the effect being more pronounced during the warm period of the year than in winter. The ratio of fluorescence to DOC increased during the warm period of the year but not in winter, and decreased rapidly with discharge at the beginning of the flood period in autumn. The results give indications of the origin, formation, nature and fate of the DOM in the river water. Temperature-dependent microbiological processes in the formation of iron-organic colloids seem to be important. (Author's abstract)

QUALITY CHARACTERIZATION OF GROUNDWATER IN KOILSAGAR PROJECT AREA, MAHABUBNAGAR DISTRICT, ANDHRA PRADESH, INDIA.
Osmania Univ., Hyderabad (India).
C. SudarsanaRaju, and P. V. PrakeshGoud.
Environmental Geology and Water Sciences EGWSEI, Vol. 16, No. 2, p 121-128, 1990. 3 fig, 3 tab, 12 ref.

Descriptors: *Groundwater quality, *India, *Water chemistry, Acidic water, Alkaline water, Anions, Bicarbonates, Calcium, Cations, Ion exchange, Irrigation water, Magnesium, Saline water, Sodium.

Studies of groundwater chemistry in the Koilsagar project area of Andhra Pradesh, India, indicate that the waters are sodium bicarbonate, sodium chloride, mixed cationic-mixed anionic, mixed cationic Na dominating bicarbonate, and mixed cationic Ca dominating bicarbonate types. Of these, sodium bicarbonate and mixed cationic Mg dominating bicarbonate types of waters are more prevalent. Isocone mapping of specific conductance indicates that the ionic concentration increases from east to west in the area. Graphical treatment of chemical data reveals that, in general, the area has basic water, whereas the left flank canal area is dominated by secondary alkaline water, and Pallamarri and Pedda Rajmur villages have strongly acidic waters. Ion-exchange studies show that cation-anion exchanges exist all over the area except for two places, which have a base exchange hardened type of water. Graphical representation further shows that most of the area has medium salinity-low sodium (C2S1) water useful for irrigation purposes. High salinity-low sodium (C3S1) and high salinity-medium sodium (C3S2) waters are present in some areas, which need adequate drainage to overcome the salinity problem. (Author's abstract)

ORIGIN AND EVOLUTION OF FORMATION WATERS, ALBERTA BASIN, WESTERN CANADA SEDIMENTARY BASIN: I. CHEMISTRY.
Alberta Univ., Edmonton. Dept. of Geology.
C. A. Connolly, L. M. Walter, H. Baadsgaard, and F. J. Longstaffe.
Applied Geochemistry APPGEY, Vol. 5, No. 4, p 375-395, July/August 1990. 16 fig, 2 tab, 87 ref. NSF Grant No. EAR-8657180 and NSERC Operating Grant Nos. A7387 and OGP1168.

Descriptors: *Alberta, *Connate water, *Geochemistry, *Groundwater chemistry, *Water chemistry, Aliphatic hydrocarbons, Brines, Carbonates, Dissolved solids, Meteoric water.

Formation waters from Devonian through Cretaceous carbonate and clastic reservoirs in the Alberta Basin were examined for short chained aliphatic acids (SCAs) and major and minor elements. The abundance and distribution of SCA's in Alberta Basin formation waters do not appear influenced or related to reservoir temperature, sampling depth or geological age. However, a strong association between SCA concentration and proximity to the Jurassic shales is evident, with water washing and meteoric flushing providing a contributing influence. The distinct water groups evident in the Alberta Basin are: (1) Group I waters which are dominantly carbonate hosted and are stratigraphically the lowest; (2) Group II waters which are primarily from clastic reservoirs; and (3) Group III waters which are completely clastic hosted and comprise the stratigraphically highest zone. Group I and II form a distinct hydrochemical regime, which is decoupled from the dilute waters of Group III. Group III water chemistry is dominated by Na and HCO3 (alkalinity). Formation waters from Group I and II form two component mixtures of residual evaporite brine and post Laramide but pre-present day meteoric water. The brine end member was formed by the evaporation of sea water beyond the point of halite saturation, and was not influenced by the congruent dissolution of evaporite deposits. These carbonate hosted waters were subsequently influenced by silicate hydrolysis and clay-carbonate reactions in surrounding shales and ankeritization reactions of reservoir carbonates. The clastic-hosted waters of Group II were affected by feldspar-clay mineral leaching reactions initiated by gravity driven flow of meteoric waters, resulting from Laramide orogenesis. Both Group I and II waters may also have been altered by ion exchange processes. (See also W91-02889) (Lantz-PTT)

Descriptors: *Alberta, *Chemical analysis, *Connate water, *Geochemistry, *Groundwater chemistry, *Isotopic tracers, *Mixing, *Sedimentary basins, *Water chemistry, Deuterium, Hydrological regime, Oxygen radioisotopes, Strontium radioisotopes.

Isotopic measurements (Sr, O, D) on formation waters from the Alberta Basin have been made, covering a stratigraphic range from Devonian to Upper Cretaceous. These measurements, combined with chemical compositional trends, give evidence for two distinct water regimes. One hydrological regime is composed of waters hosted in Devonian-Lower Cretaceous reservoirs, the other waters from Upper Cretaceous and younger sedimentary rocks. The waters within the Devonian-Lower Cretaceous regime exhibit a large range in 87-Sr/86-Sr values (0.7076-0.7129), but have similar Sr concentrations, regardless of host lithology. Bulk rock and late stage diagenetic cements are less radiogenic than present brines. Importantly, brines from Devonian carbonates possess the most radiogenic Sr isotopic signatures of the waters examined. Devonian shales and/or Cambrian shales may be sources of high 87-Sr/86-Sr ratios in the carbonate hosted waters. Waters from the upper Cretaceous clastic units, which have ratios as low as 0.7058, and diagenetic cements from Upper Cretaceous clastic units appear to have precipitated from fluids similar in Sr isotropic value to modern brines. Waters in upper Cretaceous reservoirs have O and D isotopic compositions similar to those of present day rainfall, which in conjunction with very dilute Sr concentrations and low Sr ratios suggest hydrological isolation from the stratigraphically lower system. SULPHUR AND OXYGEN ISOTOPES OF DISSOLVED SULPHUR SPECIES IN FORMATION WATERS FROM THE DOGGER GEOTHERMAL AQUIFER, PARIS BASIN, FRANCE.
Bureau de Recherches Geologiques et Minieres, Orleans (France).
C. Fouillac, A. M. Fouillac, and A. Criaud.
Applied Geochemistry APPGEY, Vol. 5, No. 4, p 415-427, July/August 1990. 6 fig, 4 tab, 40 ref. Bureau de Recherches Geologiques et Miniers DG 12 EN3G 0033F, and The Commission of the European Communities Contract EN4G 0038F.

Descriptors: *Connate water, *France, *Geochemistry, *Geothermal water, *Groundwater chemistry, *Isotope studies, *Oxygen isotopes, *Sulfur, *Sulfur isotopes, *Water chemistry, Aquifers, Paris Basin, Sulfates, Sulfides, Sulfur compounds.

Isotopic analysis of the S in sulfides and sulfates from formation waters were made at 35 geothermal wells exploiting the Dogger geothermal aquifer of the Paris Basin. Isotopic analysis of the O of the dissolved sulfates was also made on 12 of these samples. The results show a distribution of the delta-34-S of the sulfates according to geographic zones that also correspond to variations in the geochemistry of the fluids, in particular, the sulfide content. Samples taken in the Seine-St-Denis area and in the areas north and west of Paris show high delta-34-S values ranging from +26.3 to +48.9%. Values of delta-34-S for sulfides range from -8.5 to 5%, and are interpreted as reflecting the effect of bacterial reduction in a confined part of the basin. Modeling this reduction by Rayleigh distillation mechanism made it possible to calculate a value of 1.038 +/-0.003 for the coefficient of fractionation between the sulfates and sulfides. An important part of the sulfides formed by bacterial reduction has been subtracted from the fluid by deposition South of Paris and in the Val de Marne, the delta 34-S values for the sulfates are more uniform ranging between 22.4 and 26.6%, despite the existence of bacterial activity. This is most probably due to a higher rate of flow of the waters, entailing renewal of the sulfate stock. The isotopic composition of the O of the sulfates for the Seine-St-Denis area and the areas west and north of Paris is very uniform, between 16.1 and 17.1%, despite the wide range in delta-34-S (26.3 to 48.9%) for the same samples. The calculated isotopic temperatures are close to those measured in situ. These results suggest either that sulfate water isotopic equilibrium was established after the reduction, or that the coefficient of O fractionation is very low (<1.00 during bacterial reduction. MODELLING OF THE EVOLUTION OF GROUND WATERS IN A GRANITE SYSTEM AT LOW TEMPERATURE: THE STRIPA GROUND WATERS, SWEDEN.
Paris-7 Univ. (France). Lab. de Geochimie des Eaux.
D. Grimaud, C. Beaucaire, and G. Michard.
Applied Geochemistry APPGEY, Vol. 5, No. 4, p 515-525, July/August 1990. 7 fig, 3 tab, 39 ref.

Descriptors: *Connate water, *Geochemistry, *Groundwater chemistry, *Model studies, *Sweden, *Water chemistry, Aluminum, Chlorides, Granites, Groundwater resources, Minerals.

From previously collected chemical data on Stripa groundwaters, a model of evolution of the chemical composition of groundwater in a granite system at low temperatures is proposed. The existence of two end-member groundwater compositions made it possible first, to test the conventional model of a geothermal system according to which an overall equilibrium between the waters and a given mineral assemblage can be defined, and then to show that such a model could be extended to low temperatures (10 C). Conversely, if the mineral assemblage is known, the equilibration temperature and the charge of the mobile ions (in this case, Cl), the composition of the solution is entirely fixed. In this model of the Stripa groundwaters, the existence of two end-member groundwater compositions can be explained by an evolution from a 'kaolinite-albite-laumontite' equilibrium to a 'prehnite-albite-laumonite' equilibrium, which requiring less Al. The Cl ion concentrations of the groundwaters, are emphasized because they can be considered as indicators of the degree of reaction progress between rock and water, thus determining the degree of equilibration of the system. MONTHLY VARIATIONS OF DISSOLVED FREE AMINO ACIDS (DFAA) OBSERVED IN THE BAY OF VILLEFRANCHE-SUR-MER, FRANCE: EXPERIMENTAL STUDY ON THEIR UPTAKE BY PARACENTROTUS LIVIDUS AND SPHAERECHINUS GRANULARIS LARVAE (VARIATIONS MENSUELLES DES ACIDES AMINES LIBRES DISSOUS (AALD) PRESENTS EN UN POINT DE LA RADE DE VILLEFRANCHE-SUR-MER: UTILISATION PAR LES LARVES DE PARACENTROTUS LIVIDUS ET DE SPHAERECHINUS GRANULARIS).
Institut Oceanographique, Paris (France). Lab. de Physiologie des Etres Marins.
J. F. Pavillon, and P. Rault.
Aquatic Living Resources ALREEA, Vol. 3, No. 2, p 147-150, 1990. 2 tab, 6 ref. English summary.

Descriptors: *Amino acids, *Bioavailability, *Echinoderms, *Estuarine environment, *Larvae, *Nutrients, *Villefranche-sur-Mer, Bays, France, High performance liquid chromatography, Seasonal variation, Water analysis.

The harbour waters of Villefranche-sur-Mer were analyzed for dissolved free amino acids dissolved (DFAA), and the consumption of DFAA by larvae was studied to establish a relationship between the concentration of the DFAA, the nature of the DFAA and their consumption by larvae. Sea water was sampled at a depth of seven meters, filtered through a 0.22 micrometer Gelman membrane filter and frozen at -70 C. Analysis was carried out by forming a fluorescent derivative with o-phthalaldehyde and 2-mercaptoethanol, followed by HPLC analysis with a fluorescence detector on a C-18 column. The mobile phase was sodium acetate and methanol. The laboratory experiments were carried out in March and October of 1986 and June of 1987, with sea water taken in December 1985, March and October of 1986 and June of 1987. The larvae were obtained by the method reported by Davis. The pluteus larvae of Paracentrotus lividus and Sphaerechinus granularis were used to study the consumption of DFAA. Paracentrotus lividus consumed 0.3 to 1.6 microcal/larvae/hr in the endotrophic phase and Sphaerechinus granularis 0.45 to 0.74 microcal/larvae/hr. During the exotrophic phase the value was 0.08 to 0.7 microcal/larvae/hr for Paracentrotus lividus. The concentration of DFAA in the sea water varied from 640 (June 1986) to 4421 (May 1987) nmole/L in the period from October 1985 to June 1987. (King-PTT)

INFLUENCE OF SEDIMENT DISTURBANCE AND WATER FLOW ON THE GROWTH OF THE SOFT-SHELL CLAM, MYA ARENARIA L.
Dalhousie Univ., Halifax (Nova Scotia). Dept. of Oceanography.
C. W. Emerson.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 9, p 1655-1663, September 1990. 4 fig, 2 tab, 42 ref.

Descriptors: *Clams, *Environmental effects, *Flow discharge, *Growth rates, *Mollusks, *Sediment distribution, *Sediment disturbance, *Sediment-water interfaces, Bottom sediments, Coastal waters, Flow velocity, Flumes, Laboratory methods, Shear stress.

The importance of sediment disturbance and water flow to the production of the soft-shell clam, Mya arenaria, was assessed in laboratory flumes by measuring growth rates of clams exposed to a gradation of bed shear stress, free-stream velocity, and frequency and depth of sediment disturbance over 10-month period. In the absence of sediment disturbance, growth of soft tissue was directly proportional to both free stream and shear velocity (r-squared = 0.64 and 0.72, respectively). Increased organic seston flux may have linked higher water flow to higher growth. In all treatments, maximum growth rates were observed with daily disturbance of the top centimeter of sediment. No level of disturbance resulted in growth rates lower than that of undisturbed clams in low flow (free stream velocity of 0.4 cm/s and shear velocity of 0.1 cm/sec). The stimulation of growth under maximum sediment disturbance was removed when free stream velocity exceeded 3 cm/sec. An energy budget for M. arenaria indicated that the amount of organic matter suspended during sediment disturbance was insufficient to account for the increased growth in clams subjected to high levels of disturbance. The sediment disturbance associated with intense clam harvesting, and changes in local hydrography resulting from coastal development, may be responsible for some of the unexplained growth variation in commercial clam stocks. SOLUBLE FLUORESCENCE: EFFECTS ON CHLOROPHYLL DETERMINATION AT DIFFERENT SALINITIES.
Rhode Island Univ., Narragansett. Graduate School of Oceanography.
A. A. Keller, L. L. Beatty, L. E. Weber, and C. A. Heil.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 9, p 1700-1709, September 1990. 8 fig, 2 tab, 31 ref.

Descriptors: *Chlorophyll, *Estuarine environment, *Fluorescence, *Laboratory methods, *Measuring instruments, *Phytoplankton, *Salinity, Biomass, Pawcatuck River Estuary, Regression analysis, Rhode Island, Sampling.

Measurements of 3-(3,4-dichlorophenyl)-1,1-dimethylurea (DCMU) enhanced fluorescence, provided reliable estimates of phytoplankton biomass along a salinity gradient when adjusted for soluble enhanced fluorescence, <1 microm size fraction. Positive linear relationships ($P<0.0001$) were observed between fluorescence and extracted chlorophyll at salinities of 0, 5, 10 and 30 in experimental mesocosms and the Pawcatuck River Estuary, Rhode Island, both before and after subtraction of soluble enhanced fluorescence. Adjusting for soluble enhanced fluorescence did not reduce variability in the DCMU enhanced fluorescence to extracted chlorophyll relationships or alter slopes of the regression equations at different salinities. Positive intercepts (which varied with salinity) were, however, reduced to zero after correction. Results further indicated that soluble enhanced fluorescence decreased with increasing salinity (primarily as a result of dilution with seawater), that it was relatively constant at a given salinity, and was unrelated to total DCMU enhanced fluorescence. Relying solely on in vivo fluorescence techniques, without correction for soluble fluorescence, would thus increasingly lead to overestimates of phytoplankton biomass at decreasing salinities. Over the experimental period, 32% (range 8 to 93%) of total DCMU enhanced fluorescence was present in the soluble fraction with the majority (83%) non-photosynthetic material and most likely dissolved humic substances. The soluble fraction and light extinction coefficients were significantly and positively related in the mesocosms and the field. (Author's abstract)

DISTRIBUTION OF SHRIMP AND FISH BY-CATCH ASSEMBLAGES IN THE CANADIAN EASTERN ARCTIC IN RELATION IN WATER CIRCULATION.
Arctic Biological Station, Ste. Anne de Bellevue (Quebec).
C. Hudson.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 9, p 1710-1723, September 1990. 7 fig, 4 tab, 45 ref.

Descriptors: *Arctic Ocean, *Canada, *Fish, *Shrimp, *Species diversity, *Water circulation, Coastal waters, Hudson Strait, Labrador, Latitudinal studies, Salinity, Water temperature.

In the Canadian eastern Arctic, the catches of common species of decapods and fish in bottom trawls reveal a continuum of increasing species richness and abundance in an easterly direction through Hudson Strait. Species richness is greatest in Ungava Bay, where Arctic and Labrador Sea components of the fauna coexist. Over the study area, species could be divided in three associations corresponding to the origin of the predominant water masses; Arctic cod, cottids, zoarcids, and liparids predominate in the Arctic waters of western and central Hudson Strait; Greenland halibut, roughhead grenadier, and three-beard rockling are characteristic of the northern Labrador Sea; pandalid shrimp are abundant in areas of deep (> 300), intensely mixed waters near the mouth of Hudson Strait. Pink shrimp (Pandalus borealis) predominates in Davis Strait-Labrador, whereas it is replaced by the striped pink shrimp (P. montagui) in eastern Hudson Strait, reflecting environmental optima in subarctic and Arctic dominated waters, respectively. The yearly catches of striped pink shrimp are highly variable, possibly related to mixing intensity in eastern Hudson Strait. In Canadian Arctic waters, species richness, distribution, and abundance are related to temperature, salinity, mixing, and general circulation of water masses. (Author's abstract)

Descriptors: *Algae, *Algal growth, *Barriers, *Check structures, *Environmental effects, *Estuaries, *Estuarine environment, *Phytoplankton, *Population dynamics, *Succession, *The Netherlands, Hydrodynamics, Light penetration, Oosterschelde Estuary, Salinity, Seasonal variation, Sedimentation, Species composition, Storm surges, Storm water management, Storm-surge barrier, Water currents.

Seasonal succession of phytoplankton was followed weekly in the eastern and western parts of the Oosterschelde estuary, before (1982-1983) and during (1984-1986) the construction of the storm-surge barrier. Construction of the barrier seriously influenced the hydrodynamics of the estuary. In the eastern part, decreased current velocities led to the emergence of a vertical salinity gradient, to increased sedimentation of suspended matter and to a rise in transparency during a prolonged period of the year. The relationship between species composition and biomass on the one hand and environmental variables on the other hand was analyzed in a Canonical Correspondence Analysis, for both compartments separately. The analysis revealed that the phytoplankton assemblage more and more obtained a summer character, extending its growth season both earlier and later in the year. The transition of spring to summer phytoplankton assemblages proceeded parallel to the main light-turbidity gradient. The light factor not only explained the seasonal pattern, but also the long-term trend from pre-barrier to barrier period. Partial Detrended Correspondence Analysis after correction for mean seasonal pattern confirmed this trend significantly. (Author's abstract)

FACTORS INFLUENCING COMMUNITY STRUCTURE AND DISTRIBUTION OF DIFFERENT LIFE-CYCLE CATEGORIES OF FISHES IN SHALLOW WATERS OF A LARGE AUSTRALIAN ESTUARY.
Murdoch Univ. (Western Australia). School of Biological and Environmental Sciences.
N. R. Loneragan, and I. C. Potter.
Marine Biology MBIOAJ, Vol. 106, No. 1, p 25-37, July 1990. 6 fig, 5 tab, 42 ref.

Descriptors: *Australia, *Estuaries, *Estuarine environment, *Fish, *Fish populations, *Life cycles, *Species composition, Population density, Salinity, Seasonal variation, Spawning, Swan Estuary, Water temperature.

Fish were collected at regular intervals over 5 yr (February 1977 to December 1981) from ten shallow water sites located throughout the lower, middle and upper regions of the large Swan Estuary in temperate southwestern Australia. Analysis of the catch data showed that the total number of species and total density of fishes were both influenced to a greater extent by site and season within the estuary than by year. The number of species and density of fishes within the whole system were greatest during the summer and autumn, when salinities and temperatures were at a maximum, and declined with distance from the estuary mouth. The density of marine estuarine-opportunists (species which enter estuaries regularly and in considerable numbers) was also correlated with temperature, reflecting the tendency for species of this category to congregate in the shallows during the summer and autumn. The similar seasonal aggregations of the single anadromous species and species that complete their whole life cycle in the estuary were frequently related to spawning. The density and number of species of the estuarine category were correlated neither with salinity nor with distance from the estuary mouth. The density of freshwater species was inversely correlated with salinity and positively correlated with distance from the estuary mouth. The composition of the fish fauna changed progressively through the estuary, with that of the lower estuary being the most discrete. The composition also changed seasonally, particularly in the upper estuary where, during the winter and spring, the volume of freshwater discharge increased greatly and as a consequence the salinity declined markedly. The species characteristic of the lower estuary were generally marine-opportunists, whereas those of the upper estuary typically belonged to either the estuarine or anadromous categories. Marine Ecology Progress Series MESEDT, Vol. 65, No. 2, p 159-170, 1990. 5 fig, 4 tab, 60 ref.

Descriptors: *Carbon cycle, *Estuarine environment, *Food chains, *Marine bacteria, Biomass, Carbon budgets, Microorganisms, Mussels, Nutrients, Phytoplankton, Primary productivity, Zooplankton.

During 9 to 25 June 1987, carbon budgets were established for estuarine enclosures manipulated by additions of nutrients and suspension-feeding bivalves. An intensive sampling program and a detailed examination of autotrophic and heterotrophic microorganisms enabled construction of carbon budgets of the microbial food web and comparison flow rates through a number of microbial components. Phytoplankton biomass and production covaried, and, as expected, lowest values were recorded in enclosures with added mussels, and highest values in enclosures with added nutrients. Bacteria and heterotrophic nanoflagellates peaked a few days after maxima in phytoplankton biomass and production. In enclosures with added mussels, biomasses were lower for bacteria and microzooplankton, and mesozooplankton, but slightly higher for heterotrophic nanoflagellates. Bacteria, flagellates, and microzooplankton, mostly ciliates, dominated heterotrophic processes, whereas larger mesozooplankton ingestion did not exceed 5% of phytoplankton primary production. Microzooplankton and flagellate clearances were higher in enclosures with added nutrients, whereas no such changes were found in the macrozooplankton, probably because the duration of the experiments did not allow full development of the macrozooplankton. The added mussels dominated heterotrophic consumption and controlled organisms >20 microns. Exclusion of mussels induced a primary dominance of microzooplankton followed by a subsequent increase of mesozooplankton. Additions of nutrients and filtration by suspension-feeding bivalves caused qualitative and quantitative changes at all levels in the microbial food web. These changes were measured from a large number of microbial components and allowed balances of the carbon budgets to be made as well as identification of factors controlling the structure and function of the pelagic carbon cycle. TIDAL AND TURBIDITY EFFECTS ON THE SHALLOW-WATER FISH ASSEMBLAGE OF KUWAIT BAY.
Kuwait Univ., Safat. Dept. of Zoology.
F. Abou-Seedo, D. A. Clayton, and J. M. Wright.
Marine Ecology Progress Series MESEDT, Vol. 65, No. 3, p 213-223, 1990. 6 fig, 8 tab, 31 ref.
Kuwait University Grant SZ027.

Descriptors: *Diurnal distribution, *Fish, *Fish populations, *Kuwait, *Marine environment, *Tidal effects, *Turbidity, Biomass, Kuwait Bay, Mud flats, Population density, Sand, Seasonal variation, Shallow water, Species composition.

Effects of location, diel period, tidal condition and water clarity on the size and distribution of the shallow water fish assemblage of the non-estuarine Kuwait Bay were investigated using a beach seine and a small research trawl during spring and summer 1989. Total numbers, biomass and numbers of species differed markedly between Doha, a sandy shore environment, and Kazmah, an extensive intertidal mud flat. When fish were present in large numbers there was a marked diel effect at both locations with many more fish captured during the night. Tidal effects were influenced by turbidity and the age structure of the assemblage. In clear water during spring, very young Liza carinata from the seine catches formed shoals at the edge of the rising tide both day and night, while fish 2 mo older formed shoals only on daytime rising tides. At Kazmah during spring, high turbidity obscured any tidal effects in the seine catches. In slightly deeper water, sampled by trawl during spring, Leiognathus decorus showed an asymmetrical tidal migration. In summer, beach seine catches were much higher on the rising tide. Summer trawl catches did not show a consistent tidal effect. (Author's abstract)

CONTROL OF MEIOBENTHIC ABUNDANCE BY MACROEPIFAUNA IN A SUBTIDAL MUDDY HABITAT.
Heriot-Watt Univ., Edinburgh (Scotland). Dept. of Biological Sciences.
E. Olafsson, and C. G. Moore.
Marine Ecology Progress Series MESEDT, Vol. 65, No. 3, p 241-249, 1990. 7 fig, 62 ref.

Descriptors: *Fauna, *Marine animals, *Marine environment, Benthic environment, Benthic fauna, Copepods, Food chains, Loch Creran, Macrofauna, Marine sediments, Meiofauna, Microfauna, Nematodes, Population density, Scotland.

In order to assess the effects of microfauna in meiofaunal community structure, field investigations were performed in a low energy subtidal muddy sediment Loch Creran, a sea-loch on the west coast of Scotland. Meiofaunal colonization of azoic sediment in cages designed to exclude macrofauna to varying degrees was studied. After 1 mo, nematode density in all 15 cages was less than a third of ambient density. In none of the cages did the nematodes reach ambient densities within the experimental period. Copepods attained background levels in 3 mo in all cages and were in higher numbers in cages designed to exclude all macrofauna. Results indicate that small to medium sized macroepifauna control the densities of copepods at the study site. (Author's abstract)

The annual above ground productivity of Spartina alterniflora in a South Carolina salt marsh varies by a factor of two, and correlates positively (r sq = 0.99, P < 0.001) with anomalies in mean sea level during the growing season. The effect of sea level anomalies on the salinity of the intertidal sediments probably accounts for the observed changes in primary production. It has also been shown that commercial landings of shrimp and menhaden from the southeastern US Atlantic and central Gulf of Mexico are positively correlated with sea level anomalies. These species use salt marsh habitats as juveniles, and the authors attribute this correlation to effects of sea level anomalies on habitat availability or food production. (Author's abstract)

Saltwater intrusion is believed to be one of the greatest threats to Louisiana's fishery and wildlife resources. The Louisiana Department of Wildlife and Fisheries has maintained salinity recording stations throughout the state's coastal marshes since the 1960's. We applied several different analytical approaches to the salinity data from 17 stations to determine whether this data base could be used to detect and quantify long-term salinity trends in coastal Louisiana. We did not detect a large-scale, consistent trend over time in coastal salinities across the state. Problems that hindered the detection of long-term trends included short periods of record and the placement of the recording stations in salt and brackish marsh areas, where we would not expect to find great changes in salinity. For the data to be useful in monitoring salinity trends in coastal marshes, especially with respect to saltwater intrusion, stations should be added in fresh and intermediate marshes. In addition, the relationships our study revealed between short-and long-term data indicate that records covering less than a decade are insufficient to denote long-term salinity changes, barring some major modification of the hydrologic regime. A. K. Masse.
Journal of Geophysical Research (C) Oceans JGRCEY, Vol. 95, No. 9, p 16,085-16,096, September 15, 1990. 12 fig, 27 ref. NSF Grant No. OCE87-11299.

Descriptors: *Barotropic models, *Delaware Bay, *Estuaries, *Estuarine environment, *Model studies, *Water circulation, Bottom circulation, Brackish water, Hydraulic models, Tidal hydraulics, Upwelling.

Coupled circulation between an estuary and the adjacent shelf is a new area of study. At low frequencies estuarine gravitational circulation requires landward flow of lower layer shelf water to balance the seaward flow of brackish estuarine water over the shelf. A clear description of the low frequency physical coupling between the estuary and shelf waters is developed through the use of a steady, linear, barotropic model. Complex bottom topography for the shelf is treated. The shelf adjacent to Delaware Bay, located on the east coast of the U.S. is used as an example. The results show that the landward flow field, driven only by withdrawal of flow through the estuary's entrance, is independent on the flow field otherwise present over the shelf. In the northern hemisphere this landward flow passes along the coast to the right of the estuary entrance, when viewed facing offshore, before it enters the estuary. Model results are supported by near bottom current observations collected on the shelf adjacent to the mouth of Delaware Bay. (Author's abstract)

Descriptors: *Atmospheric circulation, *Delaware Bay, *Estuaries, *Tidal hydraulics, *Tides, *Wind tides, Estuarine environment, Oceanography, Wind pressure.

Until recently, most oceanographic research relating to the tidal variability in an estuary has ignored the effect of atmospherically forced motions on tidal motions. Mechanisms exist through which high frequency wind waves and low frequency subtidal variability can interact nonlinearly with the tide, and modify the tidal response of an estuary significantly. A set of current and sea level observations in the upper Delaware Bay provides observational evidence which suggests that tidal variability in the interior of the bay was appreciably modified during two moderately strong atmospheric events. The observed order of magnitude of changes in tidal characteristics can be explained by interactions of the tide with surface waves and subtidal motions. The dominant mechanism in wave current interaction is the turbulent wave boundary layer, which enhances the frictional attenuation of the tide. Changes in propagation and attenuation characteristics due to subtidal depth changes have a smaller but still observable effect. (Lantz-PTT)

Descriptors: *Adriatic Sea, *Hydrology, *Italy, *Lagoons, *Lakes, *Multivariate analysis, *Phytoplankton, *Seasonal variation, Coastal environment, Diatoms, Dystrophic lakes, Lake Varano, Nanoplankton, Physicochemical properties, Picoplankton.

A 12-month study was made on the principal environmental factors affecting the physico-chemical properties and phytoplankton of Lake Varano. High levels of oxygenation, nitrates and phosphates with uniform levels of pH and salinity contributed to the high density of phytoplankton during the entire study period. Picoplankton, nanoplankton and diatoms were dominant especially during summer. Multivariate analysis of the data indicated that both the physico-chemical and biological conditions of this environment are greatly influenced by the seasons. Also, the two mouth canals are major factors that cause the dystrophic characteristics of this lake. Compared with other Italian coastal environments, this area is scarcely affected by anthropogenic factors. (Medina-PTT)

Descriptors: *Desalination plants, *Desalination wastes, *Flash evaporation, *Separation techniques, *Waste recovery, *Water reuse, Brines, Magnesium compounds, Mathematical models, Potable water, Saudi Arabia, Simulation analysis, Sodium chloride.

Salt recovery from rejected brines of the Al-Khobar Water Desalination Plant, Saudi Arabia, is studied through the simulation of a modified multistage flash evaporator system. Two phases of concentration are planned: Phase I will concentrate the main effluent from 6.4 wt% total salt to 28.8%, while Phase II will use the effluents from Phase I as a feed to undergo further evaporation and cooling. NaCl and water are produced throughout this phase, while the end residue product will be essentially MgCl2, since it is the most soluble. A mathematical model is developed and used to perform stage-to-stage material and heat balance calculations. Concentrations of NaCl and MgCl2 in the streams entering and leaving a stage are determined by using the solubility correlation developed in Part I. Simulation results show that by using 5210 tons/h brine as a feed for Phase I, 4430 tons/h fresh water, 277 tons/h NaCl and 502 tons/h 'bittern' (in which the ratio of MgCl2/NaCl is increased to 12) are recovered as the very final products of the integrated scheme. This bittern provides 30 tons/h MgCl2 as an end product. (Author's abstract)

Descriptors: *Developing countries, *Sahel, *Water holes, *Water supply, *Water tanks, Cattle, Evapotranspiration, Groundwater, Management planning, Social aspects, Water conservation.

In the Sahelian cattle breeding areas, the exploration of natural resources must emphasize their fragility and must spread the sampling in space and time. The concentration of cattle around water points leads to the degradation of surrounding pastures. A study of water transfers made two main points clear: (1) loss of water by evapotranspiration can be higher than 2000 mm and (2) surface runoff constitutes an abundant water resource. To spread the water resource in time and space, small equipment is proposed (tanks, overdeepening of pools). By taking account of traditional breeding systems in this way, recourse to the exploitation of underground resources often can be avoided, thus eliminating the need for development of technical and sociological infrastructure that the society cannot support. Descriptors: *Aquifer management, *Artificial recharge, *Groundwater management, *Groundwater resources, *Water harvesting, *Water resources management, *Water supply development, Drawdown, Economic aspects, Ephemeral streams, Groundwater recharge, Hydrologic budget, Hydrologic models, Model studies, Nevada, Runoff, Surface runoff, Watershed management.

The economic and technical feasibility of harvesting ephemeral runoff for artificial recharge of overdrafted aquifers in a topographically closed basin in western Nevada were investigated. Groundwater provides 80% of domestic water for the basin's 15,000 residents. Spring runoff, which is highly variable and of short duration, does not occur during peak demand periods thus precluding direct utilization. Because there are no surface storage reservoirs, the runoff is lost to evaporation from shallow, valley-bottom playas. Use of overdrafted aquifers to store harvested water and supplement supplies appears economically feasible compared to costs for alternate supplies. Donor area water balance and groundwater models which were developed indicate significant harvestable water. Groundwater simulation and geochemical models were used to select best recharge locations and study recharge effects. It was determined that, with this artificial recharge scenario, water levels in the central and northern portion of the valley would continue to decline but at a lower rate, experiencing up to 3 m less drawdown than without recharge operations. 3C. Use Of Water Of Impaired Quality

RAPID EVALUATION OF SALT TOLERANCE OF MANGROVE-SWAMP RICE VARIETIES.
Regional Mangrove Swamp Rice Station, Rokupr (Sierra Leone).
M. P. Jones.
Tropical Agriculture TAGLA2, Vol. 67, No. 3, p 199-202, July 1990. 3 fig, 2 tab, 12 ref.

Descriptors: *Developing countries, *Mangrove swamps, *Plant water potential, *Rice, *Roots, *Salinity, *Salt tolerance, Physiological ecology, Plant growth, Resource conservation, West Africa.

In West Africa, an estimated 1,500,000 ha of cultivatable mangrove swamps are affected by salinity. The identification or development of salt-tolerant rice varieties could be of considerable benefit in the stabilization of rice production and expansion of cultivatable areas in mangrove swamps. Salinity tolerance of rice varieties was determined by comparative measurement of seedling root growth in saline and in non-saline conditions. A tolerance ratio (TR) of root growth after four days in 80 mM sodium chloride solution to root growth after four days in normal culture solution was calculated for each individual within a variety. The technique was used to screen 1058 varieties/advanced lines available at the WARDA-Rokupr Station and was found to be reliable, rapid and simple. Substantial variation in seedling tolerance to salinity was found within and between varieties and populations bearing the same variety name. The seedling TR was correlated with the visual scores ($r = 0.80$, $df = 1058$, $P < 0.001$) of salt symptoms and survival ($r = 0.75$, $df = 1058$, $P < 0.001$) at 80 mM sodium chloride solution. The scores after four weeks of plant exposure to 80 mM sodium chloride confirm the ranking of the varieties on the

basis of the TR. While visual scores can be subjective, the TRs were obtained from root length which is a quantitative characteristic. Humidity and temperature appeared to affect the germination and rate of root growth, thereby affecting the TR. The changes in TR due to seasonal drift were overcome by adjusting the TRs of all test varieties with the TR of the tolerant check. The method of comparing rate of root growth of one-week-old rice seedlings in normal and 80 mM sodium chloride solutions provided a quick, reliable and simple technique of screening rice varieties and breeding lines for salinity tolerances. GROUNDWATER MANAGEMENT STRATEGY FOR SALINITY MITIGATION IN THE VICTORIAN RIVERINE PLAIN, AUSTRALIA.
Rural Water Commission of Victoria, Armidale (Australia).
R. S. Evans, and J. Nolan.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 487-499, 5 fig, 2 ref.

Descriptors: *Aquifer management, *Groundwater management, *Groundwater resources, *Irrigation effects, *Irrigation water, *Saline groundwater, Saline soils, *Water resources management, Water supply development, Australia, Conjunctive use, Groundwater irrigation, Groundwater potential, Groundwater recharge, Land use, Resource allocation, Water allocation, Water table rise, Waterlogging.

Groundwater management for salinity purposes requires a significant change of thinking compared to management for 'stressed' aquifers. The recognition that groundwater quality decrease is a primary factor controlling groundwater quantity allocation represents a significant change of thinking compared to conventional management philosophies. The need for careful management of the re-used groundwater is paramount. The long-term viability of agriculture in the Riverine Plain of Northern Victoria, Australia, is now threatened by land salinization and waterlogging; a direct result of increased rates of recharge to groundwater in response to clearing of natural vegetation and intensive irrigation. Without large scale dewatering, the groundwater system is unable to dissipate the increased recharge, hence water tables will continue to rise and exacerbate the existing problem. A groundwater management strategy is based on encouraging groundwater development. The principle constraints on such development are the need for control of aquifer salinity and salt export, in the context of an overall conjunctive use policy. Specific strategy initiatives to encourage an appropriate and sustainable level of groundwater use include: integrated water allocation and management policy, definition of salt export criteria, and community education. WATER CONSERVATION IN DROUGHT-STRICKEN SANTA BARBARA COUNTY--RESPONSE IS SLOW.
Lawrance, Fish and McFarland, Inc., Santa Barbara, CA.
W. H. Lawrance.
Public Works PUWOAH, Vol. 121, No. 10, p 102-103, September 1990. 3 tab.

Descriptors: *California, *Domestic water, *Water conservation, *Water shortage, *Water use, Analytical methods, Biochemical oxygen demand, Conservation, Environmental protection, Municipal water, Water demand.

For several years, most of the public water supply agencies in Santa Barbara County, California have encouraged their customers to conserve water. The urgency for consumer conservation has increased since 1988, and has become critical for portions of Santa Barbara County that rely to a significant extent on surface water supply. Enlisting the cooperation of all municipal sewering agencies within Santa Barbara County, Lawrance, Fisk and McFarland, Inc. obtained and analyzed municipal wastewater treatment plant data for 1983 to 1989 in order to study interior water usage. Average dry-weather flow, estimated tributary population, and representative influent concentrations of 5-day biochemical oxygen demand and suspended solids were examined. The year 1983 was selected because is was the most recent very wet year in Santa Barbara County. Using the data submitted, per capita wastewater flows and organic contributions for each year were calculated. Results showed that only one community was experiencing significant effects of interior water conservation, as registered by a consistent decrease in average dry-weather flow and per capita wastewater flows and a corresponding increase in influent biological oxygen demand. The water purveyor serving this particular community had an unusually aggressive retrofit campaign for toilets and shower heads for a number of years. This activity apparently was paying off in terms of reduced interior water usage. (Mertz-PTT)

3E. Conservation In Industry

MODELS FOR A RATIONAL UTILIZATION OF HIGH QUALITY GROUNDWATER RESOURCES.
Dortmund Univ. (Germany, F.R.). Inst. for Environmental Protection.
I. Heinz.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 515-522, 1 tab, 3 ref.

Descriptors: *Germany, *Groundwater management, *Groundwater resources, *Industrial water, *Model studies, *Taxes, *Water conservation, *Water resources management, *Water use efficiency, Drinking water, Economic justification, Water allocation, Water demand, Water pollution.

Increasing demands are being placed on high grade quality drinking water, as a result of the continuing pollution in the Federal Republic of Germany. Consequently, the need has arisen for water utilization to become as efficient as possible. Approaches in this direction have already been made in industry where engineers have intensified the search for water-saving techniques in the manufacturing process. Optimal allocation of water resources may be achieved by introducing a groundwater intake levy in order to push industry in particular towards a maximally efficient water utilization. The starting point is a supply deficit of high quality groundwater in any given area due to increasingly higher drinking water needs and/or growing pollution of water by toxic substances. Using the example of a regional model, the conditions for an economically effective allocation of water resources for both industry and the public water supply, can be seen from an ecological standpoint. The optimal rate for a water intake levy is determined with the assistance of an iteration procedure. In 1988, a water intake levy was introduced in the State of Baden-Wurttemberg in the Federal Republic of Germany. The levying of this charge on all water users (on both groundwater and surface water) is now being retrospectively justified by the argument that a more efficient utilization of water has been created and that, in the future, the price of natural resources should no longer be fixed at zero. Such a levy can only bring about a more thrifty utilization of precious water supplies. (See also W91-02672) (Fish-PTT)

SCREENING FOR DROUGHT TOLERANCE: SOYBEAN GERMINATION AND ITS RELATIONSHIP TO SEEDLING RESPONSES.
Alabama A and M Univ., Normal. Dept. of Plant and Soil Science.
B. K. Kpoghomou, V. T. Sapra, and C. A. Beyl.
Journal of Agronomy and Crop Science ZAPFAR, Vol. 164, No. 3, p 153-159, April 1990. 4 fig, 1 tab, 14 ref. CSRS/USDA Grant No. 2-01-14-3151.

Descriptors: *Crops, *Drought resistance, *Soil-water-plant relationships, *Soybeans, Drought effects, Germination, Leaves, Osmoregulation, Plant growth, Plant water potential, Stress, Vegetable crops, Water use.

Soybean has a peak daily water use of 8.5 ml during the growing season and is very sensitive to water stress. Seventeen determinate soybean (Glycine max L.) cultivars from maturity groups V through VIII were screened for drought tolerance during germination and seedling stages. Ultimately, this information may be used to predict the field performance of selected varieties under actual drought conditions. Germinating seeds and hydroponically-grown seedlings were subjected to osmotic stresses of about 0.3 and 0.5 MPa using polyethylene glycol M.W. 8000. Genotypic variability was found among the cultivars for all the parameters analyzed in both germination and seedling tests. Germination stress index was lower for seeds exposed to about 0.5 MPa than for about 0.3 MPa osmotic stress. Lower osmotic potential in the treatment medium was also correlated with lower leaf water potential in seedlings. A significant relationship was found between fresh weight and height stress indices. The cultivars that grew taller under drought stress conditions had greater dry matter accumulation and higher germination stress indices, indicating the reliability of height to predict cultivar performance under such conditions. In the seedling tests, there was no strong relationship between the leaf water potential and the overall performance of the plant, suggesting no clear osmoregulatory mechanism. (Author's abstract)

Descriptors: *Corn, *Crops, *Drought resistance, *Plant growth, *Plant water potential, *Soil-water-plant relationships, *Water stress, Absorption, Leaves, Photosynthesis, Vegetable crops.

Yield reduction caused by plant water stress can be attributed directly to inhibition of the carbon dioxide uptake rate. The effect of plant water stress on net photosynthesis and leaf growth were investigated in order to determine how much leaf water potential during vegetative growth and silking affects maize development. Two commercial maize hybrids grown in pots in a glasshouse were subjected to leaf water potentials of approximately 1300 and 1700 kPa during the eighth leaf stage and during silking to approximately -1700 and -2300 kPa to previously unstressed, moderately, and severely stressed plants. The effect of stress on inhibiting carbon dioxide uptake rates and leaf areas, as well as the recovery after alleviating stress, were compared to that of unstressed plants. No substantial differences in carbon dioxide uptake rates were found between medium and long seasoned cultivars. The carbon dioxide uptake rates per unit leaf area decreased to negative values under both moderate and severe stress conditions during both growth stages. During silking, the recovery of carbon dioxide uptake rate was much lower than during the eight leaf stage. Leaf area decreased

proportionally with increased stress but did not recover after alleviating stress on plants stressed during both the eighth leaf and silking stages. These findings indicate increased resistance to water stress with increased plant age. (Author's abstract)

WATER VAPOR TRANSPORT THROUGH A FLAIL-CHOPPED CORN RESIDUE.
Wisconsin Univ., Madison. Dept. of Soil Science.
C. B. Tanner, and Y. Shen.
Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 945-951, July/August 1990. 4 fig, 29 ref.

Descriptors: *Corn, *Evaporation, *Water transport, *Water vapor, Conductance, Convection, Crop residues, Crops, Evapotranspiration, Field tests, Flail-chopping, Regression analysis, Vapor pressure, Wind velocity.

Crop residue at the soil surface is known to decrease evaporation, and measurements have shown that wind increases evaporative loss through residues; however, measurements of water vapor flux through residues have not defined their vapor conductance. Water vapor transport through crop residues was measured in a wind tunnel and under natural wind in order to parameterize the vapor conductance in a way useful for modeling the energy balance of conservation-tillage systems. The vapor conductance of flail-chopped corn (Zea mays L.) residue laid over large vapor sources (0.15 by 1.2 m) at different vapor pressure gradients was measured in still air and under winds. In still air, the vapor conductance of 10 samples of residue (areal density, 0.4 kg/sq m; average thickness, 11 mm) averaged 2.2 mm/s at 20 C and was not significantly different than the conductance of a similar thickness of air. Error in the measurement (CV=13%) was sufficient that porosity and tortuosity effects could not be determined. Buoyancy-driven convection in the flail-chopped residue was negligible under much greater buoyancy instabilities than are likely to occur in the field. The vapor conductance of nine samples of residue measured in a wind tunnel increased linearly with wind speeds measured at 1 m above the residue. The regression coefficients of vapor conductance versus wind found in the wind tunnel and under natural winds did not differ. It is suggested that conductance measurements of other residues would be done much more easily in a suitable wind tunnel than in the field, and with the same results. (Author's abstract)

IMPACT OF WATER CONTROL ON NAVAJO IRRIGATION PROJECTS.
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
J. W. Leeper.
IN: Indian Water Rights and Water Resources Management. Proceedings of a Symposium. American Water Resources Association, Bethesda, Maryland. 1989. p 165-174, 1 fig, 6 tab, 11 ref.

Descriptors: *Agricultural water, *Indian reservations, *Indian water rights, *Irrigation practices, *Water management, *Water resources management, Navajo Indians, Social aspects.

Navajo irrigation systems have been plagued with poor performance. Many theories have been proposed to explain this poor performance including: small economically non-viable farm size, lack of maintenance, lack of funding, institutional conflict, lack of extension/technology, lack of credit, lack of education, and/or irrigated agriculture is culturally unaccepted. Based on past experience with Navajo irrigation, many authorities do not believe that small-scale irrigated agriculture is culturally or economically viable. Based on system-wide data from 83 Navajo irrigation projects, farm data from over 600 Navajo farmers and comparisons with non-Navajo systems, one of the primary constraints on these systems is a lack of physical and organizational control over water. Resources expended on education, extension or exotic crops, will have little impact on farm performance if water control is lacking. On the Navajo Reservation, in spite of small farm size, because of no access to financing and insufficient extension services, farmers who have control of their water are using it. The farms at the head of the Fruitland system, for instance, have a cropping intensity of almost 80%. Even on the Fruitland system, although the water supply is adequate, it is not reliable, nor is it distributed equitably. Without water control, most of the farms experience crop threatening water shortages sometime during the water season. (See also W91-02262) (Lantz-PTT)

IRRIGATION TRIALS: BASIS FOR THE DESIGN OF FURROW SYSTEMS.
Irrigation Development Authority, Accra (Ghana).
H. K. Nyaledzigbor.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 343-351, 5 fig, 2 tab, 2 ref.

Descriptors: *Agriculture, *Furrow irrigation, *Ghana, *Irrigation design, Design criteria, Developing countries, Economic aspects, Infiltration, Semiarid lands.

Applied research was carried out to investigate water intake, furrow lengths, and gradients for the design of a furrow irrigation system. The study aimed to develop well-designed fields with furrows of economical length and gradient and to investigate the operational parameters of lead stream size and duration to assist operational planning for the irrigation system. Furrow trials were established on the soils of an irrigation project during its design phase (semi-arid savanna zone of Ghana). The trials measured cumulative infiltration by furrow infiltration tests and investigated lead stream sizes for various furrow lengths and gradients. From the trial results it was possible to select an adequate furrow length and gradient for the layout design of the project. It also was possible to recommend the range of lead streams to achieve adequate water application, as follows: (1) the field layout of the upland areas of the project be approximately 200 m long at 1 in 500 gradient in the furrow direction; (2) furrows should have broad flat bases between ridges; (3) a lead stream of 2-2.3 l/sec should be adequate for furrows of 1-m spacing; and (4) an irrigation frequency of 4 days would be appropriate. Water use on sparse dryland crops is an important aspect of the hydrology of semi-arid zones because it is closely linked with crop yield. Information on the energy and water balance of Sahelian landscapes is needed to improve the accuracy of the output of global climate models that predict such phenomena as desertification. To improve the description of the energy balance and evaporation from sparse vegetation a collaborative project was undertaken between the Institute of Hydrology (IH), United Kingdom, and the ICRISAT Sahelian Center in Niger. The principal aim of the project was to make detailed measurements of plant, soil, and total evaporation in a sparse millet crop. Measurement techniques included the use of state-of-the-art eddy correlation devices ('The HYDRA') developed at IH, porometry to measure transpiration, and the use of microlysimeters to measure soil evaporation. Some preliminary results are presented showing how the energy balance and evaporation changed after rainfall and how the components of the total evaporation varied widely with soil wetness. The Hydra was able to provide routine measurements of evaporation and sensible heat flux to an accuracy of around 10%. The porometry and lysimeter techniques showed good agreement with the Hydra results and permitted the separation of soil from plant evaporation. The results demonstrated clearly the importance of soil evaporation in the water balance of areas covered by sparse vegetation. (See also W91-02288) (Rochester-PTT)

Upper Borgou is part of the subsahelian area. a dry tropical climate but with little variabil-5% over a long period). The annual rainfall is ge (900 mm) with a high seasonal concentra-Consequently, farmers must sow after the first tant rainfall. There are two types of soils, al and tropical ferruginous, very concretionvith a useful water reserve varying between nd 180 mm. The potential evapotranspiration) is very high between the end of the harmatriod and the beginning of the rainy season. water assessments of soils calculated for an ge year and for wet and dry years compared agricultural calendars. As a result of this comparison of the high variability of rainfall and the length of rainy seasons over the past 10 yr, farmers have adopted mobile agricultural calendars that begin with a useful water reserve approximately more than 50% of the total evapotranspiration. This empirical practice is based on the observation of depth of the moisture of soils and a very approximate evaluation of the quantities of rainfall. One question is whether it is risky that this estimation corresponds to a single measure of the recharge of the soil (50% of PET). This appears to be the result of the close knowledge farmers have of the hydrodynamic characteristics of the soils they cultivate. (See also W91-02288) (Rochester-PTT)

AGRICULTURAL WATER USE MONITORING THROUGH LANDSAT SURVEILLANCE.
Earth Technology Corp., Long Beach, CA.
R. Kelly.
IN: Remote Sensing Applications for Consumptive Use (Evapotranspiration). Papers Presented at 21st Annual AWRA Conference and Symposium, August 11-16, 1985, Tucson, Arizona. AWRA Monograph Series No. 6, (1985). p 65-72, 5 fig, 3 ref.

Descriptors: *Agricultural water, *Arizona, *Consumptive use, *Landsat images, *Remote sensing, *Satellite technology, Geographic information systems, Water resources management, Water rights.

Arizona's massive water consuming economy is a paradox to its arid environment. Agriculture is the single greatest user of the limited water resources, yet the extent of water use can be difficult to ascertain. However, agriculture is readily detectable through Landsat data analysis. A water rights geographic information system (GIS) when combined with satellite surveillance can assist in water rights determinations, water law enforcement and water use estimates. The combination of Landsat and GIS is becoming a more familiar approach to natural resource management techniques. The contemporary nature of satellite data can accommodate surveillance purposes or other new real-time assessments of resource conditions. By recombining data sets and establishing Boolean relationships between Landsat and GIS data, a vast amount of synthetic information can be visually and statistically captured. As with many GIS based natural resource management programs, many supplemental programs can be supported with data designed for an initial purpose. (See also W91-02594) (Lantz-PTT)

INFLUENCE OF THE HERBICIDE PARAQUAT 'GRAMAXON' ON GROWTH AND METABOLIC ACTIVITY OF THREE CHLOROPHYTES.
Institute of Oceanography and Fisheries, Cairo (Egypt). Lab. of Aquatic Plants.
E. A. Ibrahim.
Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 89-93, May 1990. 1 fig, 21 ref.

Descriptors: *Algae, *Aquatic weed control, *Chlorophyta, *Herbicides, *Metabolism, *Paraquat, *Plant growth, Bioassay, Chlorophyll a.

The acute toxicity of the commercial herbicide, paraquat, commonly used in the control of aquatic weeds, was determined by 96 hour static bioassay on the freshwater chlorophytes Scenedesmus dimorphus, Scenedesmus quadricauda and Ankistrodesmus falcatus. The 96 hour EC50 values of paraquat for reducing growth and metabolic products of the three algae were determined. The number of days required for cell division increased with increasing paraquat concentration. The three algae and their test parameters respond differently to paraquat. Scenedesmus dimorphus was the most susceptible alga and the chlorophyll a was the most sensitive response parameter. On the other hand, the dry weight of the test algae was the most resistant parameter. The effective dose for controlling macrophytes is 1 mg/L. The results show that application of paraquat causes an inhibitory effect in primary producers. (Author's abstract)

Descriptors: *Flood recurrence interval, *Floods, *Rainfall, *Storm runoff, *Tennessee, Flooding, Peak discharge, Streamflow.

Rainfall amounts of over 5 inches the night of February 13 and the morning of February 14, 1989, caused flooding in areas of Middle and West Tennessee. The towns of Lebanon in Middle Tennessee and Obion in West Tennessee were most severely affected. Most of the business district in Lebanon and many residential areas in Obion were flooded. Recurrence intervals for 24-hour rainfall totals were as high as 25 years at some sites but most peak discharges had recurrence intervals of less than 10 years. Rainfall amounts for the period February 13-20, 1989, peak stages and discharges for this flood, the peak of record, and a list of discharge measurements made during the flood are documented. (USGS)

IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 330-342, 4 fig, 16 ref. English summary.

Descriptors: *Agriculture, *Flood plain management, *Floods, *Land use, *Water resources development, *West Africa, Acidic soils, Casamance, Developing countries, Gambia, Guinea, Sahel, Saline soils, Sudan.

From the northern border of the Sahel to the forested areas in the south of Guinea, wet areas in Africa are being cultivated increasingly. The development of farming in the river beds is linked to constraints on rain farming on the slopes, drought in the north, exhaustion and erosion of the soil, or a shortage of arable land on the slopes in the areas with a more favorable climate. In the Sahel and the Sahelo-Sudan, drainage areas are usually spread out, rarely confined. Floods are sudden and large, and drainage in submerged areas often is slowed by topographical thresholds downstream. Temporary flooding feeds inter-flux expanses of water in the depressions. The relatively wooded flood plains are used as secondary pasture by shepherds in the north, whereas further south this is rivaled by agriculture (e.g., gardens and small rice fields). In the Sudano-Guinean region, the flood plains usually are more confined. The flood plains are affected by the rise or lateral flow from the expanses in depressions and the convergence of surface streams. Where the river bed has been transformed by human intervention, cash crops such as rice, cotton, and maize often are grown. The flood plains along tidal reaches of Gambia and Casamance and in coastal Guinea are the home of important development programs. These improvements should solve problems of acidification and salinity of the soil. (See also W91-02288) (Author's abstract)

WATER RESOURCES MANAGEMENT IN NIGERIA: THE RIVER BASIN APPROACH.
Ibadan Univ. (Nigeria). Dept. of Geography.
A. Faniran.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 836-845, 4 fig, 1 tab, 13 ref.

Descriptors: *Dams, *Nigeria, *River basin development, *Water resources development, Agriculture, Industry, Management planning, Monitoring, Reservoirs, Storage reservoirs, Water supply.

Nigeria's water resources are currently being developed for many purposes, including domestic, agricultural, and industrial uses. Irrigation activities in the north of the country have been widely reported, but more recent activities by river basin development authorities have not been so reported. Projects of the Upper Benue River Basin Authorities in the Gongola Basin (Kuri, Dadi Kowa, and Cham projects) are highlighted. Each river basin authority is currently engaged in 2-3 large-scale projects and numerous small-scale projects (earth dams, wells, boreholes, channel improvements, etc.). The Dadi Kowa scheme has the second largest storage, after Kainji Dam, in Nigeria. The Cham earth dam is one of many small-scale dams the authority has either constructed or proposed for construction. With persistent and well-guided efforts, the nation's water resources shortly will be fully controlled and ready to best serve the needs of the population. In the future, river basin authorities will need to be strengthened, both materially and in personnel, to perform other functions within the river systems, such as development of an efficient data management system and, perhaps more importantly, comprehensive planning, execution, and monitoring of the environmental impacts of development projects, as well as the observation and recording of natural processes. POSSIBILITIES FOR REGENERATION OF FLOODPLAIN FORESTS WITHIN THE FRAMEWORK OF THE FLOOD-PROTECTION MEASURES ON THE UPPER RHINE, WEST GERMANY.
Institute for Floodplains Ecology, Rastatt (Germany, F.R.).
A. Zinke, and K. A. Gutzweiler.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 13-20, June 1990. 3 fig. 5 ref.

Descriptors: *Flood plain forests, *Flood plain management, *Forest management, *Germany, *Reforestation, *Regeneration, *Rhine River, *Soil-water-plant relationships, *Water resources management, Flood control, Flood plains, Forest watersheds, France, Management planning, Polders, Revegetation, Weirs.

The Upper Rhine valley in Germany is one of the most densely populated areas in Europe. As a result, human interference has significantly reduced both the original species diversity as well as the ecological function of the floodplain forests in the area. Furthermore, past mismanagement and potential flood danger necessitates the adoption of new management policies concerning this type of landscape. Among these measures, Germany and France have planned extensive specialized flood-protection strategies including the construction of polders and the utilization of weirs. In addition, the Institute for Floodplains Ecology has proposed the relocation of existing dams which would achieve a much more effective flood practice. It is concluded that with proper future planning and well-selected flood-protection procedures, the floodplain forests could potentially be regenerated. (D'Agostino-PTT)

POTENTIAL FOR ENHANCING RIPARIAN HABITATS IN THE SOUTHWESTERN UNITED STATES WITH WATERSHED PRACTICES.
Rocky Mountain Forest and Range Experiment Station, Tempe, AZ. Forestry Sciences Lab.
L. F. Debano, and L. J. Schmidt.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 385-403, June 1990. 3 fig, 40 ref.

Descriptors: *Flow control, *Forest ecosystems, *Land management, *Riparian vegetation, *Riparian waters, *Streamflow, *Streams, *Watershed management, Channelization, Ephemeral streams, Hydrology, Stream discharge, Stream improvement.

Riparian communities are unique and sensitive habitats that are strongly interrelated with the surrounding watershed. Currently, since previous misuse has led to their extensive degradation, management of riparian areas is a critical issue in the southwestern United States. Potential opportunities for better management of existing ecosystems or for the re-establishment of new riparian communities generally exist where either the amount of water or the duration of streamflow, or both, can be increased. Various-sized channel structures, ranging from small gully check dams to large flood control structures, have been used successfully for both stabilizing erodible channels and lengthening streamflow duration. Such channel structures trap sediment in upstream deposits which store water and release it slowly over time, thereby producing perennial flow in previously ephemeral streams. In addition, the deposited sediment also provides a nutrient-rich medium which further favors plant establishment and growth. The amount and duration of streamflow through a riparian zone can also be increased by manipulating upslope vegetation where deep-rooted plants are replaced with more shallow-rooted species using less water. Such watershed practices may potentially improve the hydrologic conditions in southwestern streams as well as enhance establishment of riparian vegetation. (D'Agostino-PTT)

ENVIRONMENTAL RIVER ENGINEERING.
University of East Anglia, Norwich (England). School of Environmental Sciences.
R. D. Hey.
Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 4, No. 4, p 335-340, August 1990. 4 fig, 17 ref.

Descriptors: *Channel flow, *Hydraulic engineering, *Regulated flow, *River channels, Canals, Channels, Flood control, Geomorphology, River mechanics, River systems.

River engineering works have often caused channel instability and adversely affected the river conservation and amenity value. Recent guidelines have advocated a more natural approach to river engineering practice, to retain a habitat diversity within the river system. While a more natural approach is desirable, a geomorphological guidance is required to ensure that the advocated changes are feasible and sustainable, both in the long and short term. The key requirement for sound environmental river engineering is a understanding of the natural processes controlling channel shape and dimensions. Examples are given in the paper to illustrate how such knowledge can be used to: (1) stabilize rivers, (2) design environmentally acceptable and stable flood alleviation schemes, and (3) restore previously canalized rivers. The basis of the geomorphological input to the assessment and design process is a river survey which determines the factors controlling ch

haracteristics and how it will respond to planned hanges. (Author's abstract)

riptors: *Geologic fractures, *Groundwater ability, *Hydraulic fracturing, *Rural areas, ter yield improvement, *Well yield, Bore-, Brittany, France, Semiarid lands.

tical analysis of the discharge values for thou-of boreholes drilled in basement complex ations shows that about 30% of the wells have ductivity of less than 1 cu m/hr and 15% only 5 cu m/hr or more. Based on most of the cts, three features were apparent: (1) in a geneous hydrogeologic and climatic context, rly-sited wells have varied results; (2) the significant yields are produced by several res generally crossed at a depth of 50 m; and he 'dry' or very poorly producing wells ed no large fractures or only fractures ed or closed by the pressure of the ground. hydraulic fracturing technique was inspired idea that increased output could be obtained ificially enhancing the hydraulic connections en the borehole and the more productive l surrounding fracture network. The hydrau-cturing consists of isolating a borehole sec-ith packers and injecting water at a pressure than the natural constraints at the investi-depth. Generally, breaking or bursting s, which opens up fissures. The injected is charged with sand, which penetrates into ssures and remains there after pressure re-lease, thus keeping the fissures open. The first experiment was conducted on eight boreholes in the south of the crystalline massif of Brittany (France). The productivity of the wells was increased by at least 13%; on four of them, it increased by 50%. A similar experiment will be conducted on 25 boreholes drilled in the basement complex of Burkina Faso, with two objectives: (1) recovery of boreholes with productivities of less than 1 cu m/hr for village water supply and (2) increase in low-discharge wells (1-3 cu m/hr) to make possible small-scale irrigation and mini rural domestic water supplies. ARTIFICIAL RECHARGE IN THE ANGAS-BREMER IRRIGATION AREA.
S. R. Howles.
Mines and Energy Review South Australia, No. 157, p 22-28, 1990. 17 fig, 3 tab, 19 ref, append.

Descriptors: *Artificial recharge, *Confined aquifers, *Groundwater management, *Irrigation effects, *Saline groundwater, Angas River, Aquifers, Australia, Bremer River, Drawdown, Groundwater recharge, Recharge wells, Saline water intrusion, Salinity.

Overdevelopment of the confined limestone aquifer underlying the Angas-Bremer irrigation area in South Australia has caused severe salinity problems. Annual water extraction in recent years has been about 16,000 ML, which has created a significant regional drawdown. This extraction has alos allowed saline waters to infiltrate from marginal areas of the groundwater basin, and induced the recirculation of irrigation water. Natural recharge is estimated to be only 25% of extraction. Artificial recharge wells are being used increasingly by irrigators to replenish the aquifer with flood waters having 500-1,500 mg/L total dissolved solids. In many places this has halved the ambient groundwater salinity. South Australia Department of Mines and Energy has developed an experimental recharge well in the area to assist irrigators in overcoming design problems with their own wells. (Author's abstract)

GROUNDWATER MANAGEMENT: QUANTITY AND QUALITY.
Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. 633p. Edited by A. Sahuquillo, J. Andreu, and T. O'Donnell.

Descriptors: *Aquifer management, *Groundwater management, *Symposium, *Water pollution control, *Water quality management, *Water resources management, Case studies, Decision making, Groundwater movement, Groundwater quality, Hydrologic models, Management planning, Model studies, Research priorities, Water quality control, Watershed management.

Increasing water needs, constraints imposed by quality for different uses, and the growing importance of contamination as a result of urban, industrial, and agricultural activities make it more and more necessary to consider aquifers as components of water resources systems to increase dependable water supplies and to preserve water quality. In order to obtain gains in efficiency, it is necessary to understand the flow and chemical processes involved in groundwater and to develop management models to simulate and optimize both quantity and quality. A symposium held in Spain 2-5 October 1989 contributed 53 papers from many different countries, addressing the following topics: the role of groundwater quantity in the decision-making process on water resources, the role of groundwater quality in the decision-making process in water resources, models for groundwater management, aquifers as components of water resources systems, and applications and case studies. These papers represent an important contribution that addresses groundwater management problems in their two crucial aspects of groundwater quantity and quality, and gives an excellent idea of the state of the art and of the direction this subject will take in the near future. ACCESS OF SMALL AND MARGINAL FARMERS TO GROUNDWATER--A FIELD STUDY.
Roorkee Univ. (India). Water Resources Development Training Center.
A. S. Chawla, C. S. Raghuvanshi, and S. A. Kumar.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 29-40, 9 tab.

Descriptors: *Agricultural water, *Farming, *Groundwater management, *India, *Irrigation water, *Supplemental irrigation, *Water resources development, Canals, Crop production, Cultivation, Economic evaluation, Horizontal wells, Pumping, Wells.

The importance of groundwater and its development has been greatly felt in India during the last few decades. Groundwater alone accounts for about 40% of the total irrigated area in the country. The most outstanding problem is that of raising the economic and social status of millions of marginal and small farmers. A large number of tubewells has been installed in alluvial areas to pump groundwater to supplement canal supplies in canal-commanded areas and to provide irrigation water outside the canal command areas. The accessibility of small and marginal farmers to groundwater was examined in western Uttar Pradesh, India, including an evaluation of the economics of various lifting devices, the water requirement of crops and the capacity of wells for different categories of farmers. An analysis of the data indicates that the small and marginal farmers constituting 62% of the sample farmers operate only 23.4% of cultivable land and own only 31% of private tubewells. Only 43% of these farmers have access to groundwater. Electrically operated tubewells are most economical. Small and marginal farmers should have a pumping capacity of 3.5-5.0 HP. GROUNDWATER MANAGEMENT BY A DUAL-PIPE SUBIRRIGATION SYSTEM.
Iowa State Univ., Ames. Astronomy Program.
D. Kirkham, and R. Horton.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 53-66, 5 fig, 1 tab, 13 ref.

Descriptors: *Drainage engineering, *Groundwater irrigation, *Groundwater management, *Irrigation design, *Model studies, *Subirrigation, *Water resources management, Boundary conditions, Evapotranspiration, Groundwater movement, Hydraulic conductivity, Hydraulic models, Laplace equation, Pipes, Saturation zone, Velocity head, Water table profiles.

Solutions to water flow problems form practical relationships useful to groundwater management. Determination of hydrological quantities for a dual-pipe subirrigation-drainage system has already been done where rectangular (slit) tubes were used. An analytical solution of Laplace's equation has been developed for appropriate boundary conditions associated with the problem of dual-pipe subirrigation and drainage extended to cylindrical tubes. The solution describes stream function and hydraulic head within the groundwater flow region and likewise the associated water table

shape. The solution is general and flexible. Response of the groundwater system can be studied relative to thickness of saturated zone, position of subirrigation and drainage pipes, crop evapotranspiration, fraction of inflowing subirrigation water that exits the drains, and the aquifer hydraulic conductivity. Calculations show how pipe spacing affects shape of water table. The general solution can also be used also to predict salt flow through the system as well as water flow. DISTRIBUTION OF AQUIFER RECHARGE FROM A CIRCULAR SPREADING BASIN UNDER TRANSIENT OPERATIONS.
Colorado State Univ., Fort Collins. Dept. of Civil Engineering.
H. J. Morel-Seytoux, C. Miracapillo, and M. J. Abdulrazzak.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 67-76, 5 fig, 6 ref.

Descriptors: *Aquifer characteristics, *Aquifer management, *Artificial recharge, *Flow models, *Groundwater management, *Model studies, *Water resources management, Groundwater basins, Groundwater movement, Groundwater recharge, Infiltration rate, Mathematical models, Numerical analysis, Recharge basins, Saturation zone, Three-dimensional model, Watershed management.

The process of aquifer recharge from a circular area has been investigated for management purposes. An approximate solution to the three-dimensional problem was obtained by matching two unidimensional flows, a vertical and a radial one. The mathematical formulation was obtained first for the case of a constant infiltration rate and then for a time-dependent rate through the unsaturated zone. The formulation led to an integro-differential equation whose solution was obtained numerically. In both cases, concrete examples illustrated the influence of the parameters on the discharge into the saturated zone and on the water table level. It was determined that anisotropy of the medium influences the mound elevation below the recharge zone and to a lesser degree the discharge. Numerical examples showed that the effect of a lower horizontal conductivity is partially compensated by a higher hydraulic head, due to a more rapid rise of the water table below the spreading basin. The lateral recharge efficiencies permit comparisons between different geometric designs. Between a rectangular and a circular basin having the same area and the same spreading perimeter the efficiency of the linear geometry is higher. The model can be used also to compare different operational schemes. (See also W91-02672) (Fish-PTT)

MANAGEMENT MODEL FOR AQUIFER RECHARGE WITH NON-CONSERVATIVE POLLUTANTS.
Baghdad Univ. (Iraq). Coll. of Engineering.
Q. N. Fattah, and H. M. Hamad.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 295-304, 10 fig, 4 ref.

Descriptors: *Groundwater management, *Hydrologic models, *Model studies, *Recharge, *Water quality management, *Water resources management, Confined aquifers, Convection, Dispersion, Groundwater pollution, Groundwater recharge, Hydrological models, Parametric hydrology, Partially penetrating wells, Path of pollutants, Plumes, Pollutant identification.

The management of aquifer recharge in conformity with particular environmental standards requires that contaminant concentration zones be identified. Theoretical solutions to the convective-dispersion equation have been examined for a substance injected by a partially-penetrating well into a confined isotropic homogeneous aquifer. A numerical solution for the concentration distribution of the substance in the aquifer was developed using an alternating-direction implicit method. The model was designed for conservative and non-conservative substances, and for different influent concentration distribution. A management model was developed combining the influent temporal concentration distribution with partial penetration ratios and extent of polluted zone in the aquifer. Various combinations of these parameters may be attempted in order to develop the appropriate concentration distribution for a given pollutant, thus enabling the engineer to perform recharge operations in accordance with environmental standards. AQUIFERS AS COMPONENTS OF WATER RESOURCES SYSTEMS.
TAHAL-Water Planning for Israel Ltd., Tel-Aviv.
J. Schwarz.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 433-441, 11 ref.

Descriptors: *Aquifer management, *Groundwater management, *Groundwater resources, *Planning, *Water resources management, *Water supply development, Aquifer characteristics, Artificial recharge, Conjunctive use, Legal aspects, Management planning, Water quality management, Water treatment.

Aquifers function within water resources systems as water sources, media of storage, and means of water quality upgrading. The role of an aquifer depends on the properties of the aquifer itself and on the properties of the system as a whole. Conjunctive use of surface water and groundwater, and artificial recharge, are the most widespread uses of aquifers as components of water resources systems. Planning techniques are available to test management plans against a set of criteria including conservation of the resource and its environment, economic efficiency and financial viability. Knowledge gaps in the planning techniques and in aquifer properties fall into two main categories: (1) properties of the soil-aquifer system, of the water supply system and of the socio-economic system; and (2) techniques for evaluation of management plans in three systems. The objectives of future research and development should include regenerative small-farm agriculture; definitions of safe yield; remedial measures to improve quality by chemical processes such as demineralization, biological in situ treatment, or mixing with imported low salinity water; long distance transport of high quality water; and development of water uses that are tolerant. Emphasis will be placed in the future on conservation, regeneration, and remedial measures. (See also W91-02672) (Author's abstract) (Fish-PTT)

REGIONALIZATION SCHEMES FOR THE MANAGEMENT OF LARGE WATER RESOURCES SYSTEMS.
Universidad Politecnica de Cataluna, Barcelona (Spain). Escuela Tecnica Superior de Ingenieros de Caminos, Canales y Puertos.
J. Carrera, L. Vives, and J. Heredia.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held a Benidorm, Spain, October 2-9, 1989. Internationa Association of Hydrological Sciences, Washington, DC. 1989. p 457-470, 4 fig, 2 tab, 14 ref

Descriptors: *Aquifer management, *Groundwate management, *Groundwater resources, *Larg watersheds, *Management planning, *Planning *Regional planning, *Water resources manage ment, *Water supply development, Compute models, Conjunctive use, Reservoirs, Simulatio analysis, Surface-groundwater relations, Wate demand.

The large size of some water resources system may make classical management simulation metl ods unrealistic or unaffordably expensive for thos systems. This is particularly true in the case strongly interacting surface water and groundwa er and when a large number of demands are su plied by a large number of water sources (rese voirs and aquifers). Most management schem either ignore the topology of the distribution ne work, thus leading to unrealistic simulations, else consider an extremely large number of comb nations, thus becoming unaffordably expensiv The concept of demand region, which takes in account both network geometry and water ava ability, overcomes these limitations. Coupling th concept with a powerfully innovative method incorporate aquifer-river interaction has led to robust approach for the conjunctive use of lar systems. (See also W91-02672) (Author's abstra

*Management planning, *Model studies, *Operating policies, *Planning, *Water resources management, *Water supply development, Drinking water, Finite difference methods, Groundwater potential, Groundwater recharge, Groundwater storage, Hydrologic models, Irrigation water, Rehabilitation, Saline water intrusion, Water demand.

Israel's national water system integrates water pumped from Lake Kinneret with two groundwater sources--the Karstic Aquifer and the Coastal Aquifer--supplying drinking water and irrigation water. In the rainy season irrigation demand drops and the surplus system capacity is used for aquifer recharge. Various multi-annual simulation techniques were used to plan an operating policy that would guarantee high reliability. The operating policy derived was based on decreasing the quantities supplied below the average potential of the sources, thus creating reserve storage in the aquifers. The Coastal Aquifer is today overexploited, which has led to seawater intrusion, salination of the fresh water wells and development of large craters in the water table. A rehabilitation program was planned by a schematic model that represents the aquifer as one 'black box.' The model was checked and detailed by a finite differences model of the aquifer. These tools are part of a hierarchic set of models and techniques used to build a new master plan for the water system of Israel. (See also W91-02672) (Author's abstract)

ensive exploitation of an aquifer frequently leads deteriorating conditions, especially in highly gressive agricultural areas where the quantity vater withdrawn for irrigation purposes is usu- several times the recharge. This over-exploita- can lead to declining water levels, severe falls umping levels, and ingress of poor quality er. Artificial recharge is a possible means of viating the over-exploitation of aquifers, since it vides storage space free of cost, avoids evapo-n losses and allows the use of the stored water ng dry periods. Artificial recharge experiments oth alluvial and limestone aquifers in Gujarat, a, were performed using spreading channels, olation tanks, and injection wells. It was demrated that the first step in promoting an artifi- recharge scheme is to perform experiments ch can lead to an understanding of conditions e aquifer system. These pilots schemes provide rmation about the physical conditions in the fer and also indicate the economic and manent aspects which need to be considered. The ects in Gujarat showed that artificial recharge chnically feasible using a number of alternative tures but the results also indicated that the ts of overexploitation and saline intrusion h have occurred due to heavy irrigation deds cannot be overcome solely by artificial re-ge. MADRID MIOCENE AQUIFER AS A COMPONENT OF THE METROPOLITAN WATER SUPPLY SYSTEM.
MOPU, Madrid (Spain). Servicio Geologico.
A. Sanchez, and M. Varela.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 547-556, 5 fig, 1 tab, 4 ref.

Descriptors: *Aquifer management, *Groundwater management, *Groundwater resources, *Madrid, *Metropolitan water management, *Model studies, *Water resources management, *Water supply development, Economic aspects, Operating policies, Pumping, Simulation analysis, Spain, Water demand, Water distribution.

The optimal operation scheme of the Madrid (Spain) aquifer has been analyzed from an economic point of view. A simulation model, including the whole system, reservoirs and aquifer, as well as the restrictions associated with the distribution network and some of the treatment plants, was constructed for the analysis. The results of the modeling efforts show that there are no significant differences, in economic terms, among various aquifer operation schemes. Nevertheless, a strategy based on intermittent high pumping rates is recommended; this would enable a more efficient utilization of an eventual groundwater concession and, at the same time, would provide the means to satisfy demand increases greater than those obtainable through any other operation rule. Descriptors: *Aquifer management, *Case studies, *Economic aspects, *Groundwater management, *Groundwater potential, *Groundwater resources, *Jordan, *Water resources management, Drilling, Geohydrology, Groundwater recharge, Model studies, Numerical analysis, Oil industry, Oil shale, Pumping, Water demand.

Oil shale is the only exploitable fossil energy resource of Jordan. Central Jordan's groundwater resources to the east of the Dead Sea were investigated in order to supply an oil shale plant with 22 million cu m/year of groundwater. The regional water balance for the two main aquifers based on hydrogeological investigations and on a numerical model indicates that the potential of the upper aquifer was previously overestimated. The present groundwater abstraction already exceeds the recoverable recharge, therefore only the minimum water demand of the plant of 5 million cu m/year can be withdrawn from this aquifer. An abstraction of the required quantity from the lower aquifer is feasible on a safe yield basis but technical aspects, i.e., deep drilling, excessively large pumping lifts as well as economic and ecological aspects have to be considered. HYDROGEOLOGICAL APPROACH TO INVESTIGATION IN KARST FOR POSSIBLE MODIFICATION OF GROUNDWATER REGIME AND INCREASE OF RECOVERABLE RESERVES.
GEOZAVOD, Belgrade (Yugoslavia).
M. Komatina.
Environmental Geology and Water Sciences EGWSEI, Vol. 16, No. 2, p 149-153, 1990. 7 fig, 5 ref.

Descriptors: *Aquifer management, *Aquifers, *Groundwater management, *Karst hydrology, *Water resources development, *Water resources management, Coastal areas, Flow control, Flow discharge, Geologic control, Groundwater movement, Groundwater reservoirs, Saline water intrusion, Saline-freshwater interfaces, Springs, Water yield.

An artificial contribution to groundwater reserves for water supply is a principal interest in modern hydrogeology. The fear of the inherent risk and uncertainty were invariably present wherever a resource was discovered in karst of a geosynclinal area; consequently progress has been limited. The reasons, however, for such a cautious approach are diminishing, because much knowledge has been obtained about these aquiferous rocks, especially through investigations in the regions of surface storage reservoirs. Better knowledge of karst features and the results achieved with surface reservoirs have indicated that large amounts of groundwater can be recovered. The conventional water investigation and recovery methods have made available only small safe yields equal to the lowest natural discharge (on the order of 100 L/sec). A reasonable use of a karst water resource and its better management cannot be considered without artificial control of the groundwater regime, i.e., without adjusting the regime to human demands. Artificial interventions in karst have generally been associated with overflow springs, which can be impounded easily and at a low cost to improve the water discharge regime. Some of the technical works in naked karst are: underground reservoirs, flow control through preferential paths, water recovery by lowering discharge level, and repumping springs. Isolation of fresh groundwater from hydrochemical sea encroachment in coastal karst districts is a difficult problem. However, water levels can be raised by damming a number of preferential waterways in certain localities, similar to those in the inland karst regions, for storage of some freshwater. This will result in a substantial decrease in saline water encroachment or in its elimination where large back water volume is involved. (Fish-PTT)

AQUIFER THERMAL ENERGY STORAGE: A NUMERICAL SIMULATION OF FIELD EXPERIMENTS IN CHINA.
Nanjing Univ. (China). Dept. of Earth Sciences.
Y. Xue, C. Xie, and Q. Li.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2365-2375, October 1990. 15 fig, 3 tab, 24 ref.

Descriptors: *Aquifers, *China, *Heat storage, *Injection-production wells, *Mathematical models, *Model studies, *Thermal energy, Heat transfer, Observation wells, Seasonal distribution, Water temperature.

Computer simulations for three seasonal aquifer thermal energy storage experiments were carried out in China. The flat-lying test site and its vicinity are covered with the Quaternary system. The test facility contains four injection-production wells, 34 observation wells and four special measuring wells at the test site. The governing equation of the mathematical model used to simulate the experiments contains convection, conduction and heat dispersion terms. For the mathematical model, the aquifer is assumed to be horizontal and of uniform thickness, with the cap rock and the rock bed above and below the aquifer are assumed impermeable to flow; aquifer properties are assumed to be isotropic and uniform in the vertical direction; flow is assumed to be steady; thermal equilibrium is considered to take place instantaneously between the water and the rock in the aquifer; and the effect of natural vertical convection due to the temperature difference between the cold and warm water is ignored. The simulated temperatures agree very well with the observed field data. Total mean values of the absolute errors are 0.5 C for the single-well experiment, 0.7 C for the double experiment and 0.4 C for the multiwell experiment; relative error ranges from 2.8% to 4.5%. The simulated production temperatures and energy recovery ratios also agree very well with the field data. The results strongly indicate the validity of the model and simulation parameters used. Heat transfer through the fluid phase by heat dispersion in the governing equation is considered. (Author's abstract)

CHARACTERISTICS OF COARSE WOOD DEBRIS FOR SEVERAL COASTAL STREAMS OF SOUTHEAST ALASKA, USA.

Oregon State Univ., Corvallis. Forest Research Lab.
E. G. Robison, and R. L. Beschta.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 9, p 1684-1693, September 1990. 7 fig, 3 tab, 28 ref.

Descriptors: *Alaska, *Detritus, *Land management, *Streams, Aquatic habitats, Fish, Fish behavior, Habitats, Resource management, Stream order, Streambeds.

Coarse woody debris (>0.2 mm in diameter and 1.5 m long) was measured along five undisturbed low-gradient stream reaches; volume, decay class, and horizontal orientation in relation to channel flow of first-order, second-order, third-order, and fourth-order coastal streams were determined. Debris were also classified into four influence zones based on stream hydraulics and fish habitats. Average debris length, diameter and volume per piece increased with stream size. Eighty percent of debris volume of the first-order and the smaller second-order streams was suspended above or lying outside the bankfull channel, while less than 40% was similarly positioned in the fourth-order stream. Approximately one-third of all debris was oriented perpendicular to stream flow, regardless of stream size. First-order, second-order, and third-order streams had a higher proportion of recent debris in the channel than the fourth-order stream, most new debris being attributable to a major 1984 windstorm. Tree blowdown had a major influence on debris distribution along the smaller storm reaches. Debris jams and accumulations in the largest stream were formed from floated debris. These characterizations are useful for evaluating the distribution and amount of woody debris associated with land-management activities. (Author's abstract)

C. Valentin, and A. Casenave.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 126-134, 5 fig, 8 ref.

Descriptors: *Africa, *Arid lands, *Rainfall-runoff relationships, *Semiarid lands, *Soil types, Burkina Faso, Infiltration, Mapping, Niger, Prediction.

The most ready way of diagnosing environmental damage in the arid and semi-arid zones of West Africa is to survey the field itself. However, a systematic method is needed to alleviate problems of definition and interpretation. A descriptive and genetic typology of surface crusts is proposed for characterizing typical unit surfaces. Also, an infiltration is established for each type of unit surface based on simulated rainfall experiments. Since each unit surface represents a part of a mapping unit, the total amount of runoff can be evaluated on the scale of a watershed. Good correlation between the measured and calculated runoff has been obtained on seven watersheds in Burkina Faso and Niger. This system provides a simple method to assess the degree of environmental (soil) degradation and to forecast the subsequent changes in hydrologic regimes. (See also W91-02288) (Author's abstract)

Descriptors: *Aquatic environment, *Ecosystems, *Environmental impact, *Reservoirs, *Water pollution effects, *Water quality, Economic aspects, Evaluation, Human impact, Population dynamics, Social aspects, Trophic level, Water pollution sources.

An examination of data obtained at the Kuibyshev Reservoir, intended for use in determining the self-purification potential of aquatic ecosystems, has provided an approach for estimating the human-induced pollution-ecosystem response relationships. At the same time, recent methodological investigations have established more precisely the methodology for studying the interaction of pollutants with aquatic ecosystems: (1) more detailed investigations of the structure of each particular trophic level with complete identification of all the organisms comprising this structure; (2) studying the ecosystem structure on a seasonal, annual and long-term basis with due regard to the population dynamics and ascertaining optimum conditions of functioning of mass and scarce species at all trophic levels; (3) establishing trophic relationships and flows of energy, matter and information within each particular trophic level and between them; estimation of the energy flow in the ecosystem and its alterations in the presence of the human-induced loading, based on the concept of spatial heterogeneity of the ecosystem, a unit of measure being a field of concentration of the pertinent species at different trophic levels as well as that of chemical components; (4) carrying out a complete inventory and an eco-technogene classification of the pollutant sources and establishing quantitative and qualitative characteristics of the flow and the pollution spectrum; (5) studying specific deformations of the ecosystem in the zone of modal sources of pollution relative to the background status; (6) estimating the total loading on the waterbody, working out the respective environmental protection measures and predicting the impacts of the socio-economic development on the water quality. PRESENT SITUATION OF THE EUROPEAN FLOODPLAIN FORESTS.

Institute for Floodplains Ecology, Rastatt (Germany, F.R.).
E. L. Wenger, A. Zinke, and K. A. Gutzweiler.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 5-12, June 1990.

Descriptors: *Data acquisition, *Ecology, *Environment, *Flood plain forests, *Flood plain, *Forest ecosystems, *Forests, *Germany, *Limnology, Austria, Forest watersheds, Hungary, Information systems, Reservoirs, Switzerland.

Although the floodplain forests of Central Europe form an immensely important ecosystem, information concerning their function is scant and they are disappearing at an alarming rate. Consequently, the Institute for Floodplains Ecology in Rastatt, Germany was commissioned to construct an extensive database of the European floodplains. To date, the study has demonstrated that, with the exception of Switzerland and Germany, no country in Europe has obtained complete information about its most important floodplain areas, its forests and their types. Although some of the countries were able to provide some incomplete but practical information (Austria, Germany, Hungary), most of them, even those where relatively large undeveloped alluvial rivers exist (i.e. France, Poland, Yugoslavia), could only supply fragmentary knowledge about their floodplain forests. Recent evidence has also indicated that river impoundment, channelization, and drainage have caused rapid loss of these forests, particularly affecting the willow and poplar communities. It is concluded that a more complete understanding of floodplain function will aid in their future protection and management. (D'Agostino-PTT)

Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 181-192, June 1990. 5 ref.

Descriptors: *Ecological effects, *Forest watersheds, *Land use, *Wetlands, Agriculture, Data acquisition, Estuaries, Forest management, Resources management, Surveys, Urbanization.

Effective national management of U.S. wetlands requires current statistics on status and trends as well as detailed wetland maps for impact a

ment and site-specific decisions. The present study demonstrates that significant changes in the amounts of wetlands and deepwater habitats have occurred in the United States since the nation's first settlement. In the mid-1970's only 99 of the original 215 million acres of wetlands remained in the conterminous 48 states. These encompassed 93.7 million acres of palustrine wetlands of which 49.7 million were forested, and 5.2 million acres of estuarine wetlands of which 0.5 million were either shrubs, scrub trees or forested. Currently, wetlands cover a land surface area approximately the size of California, with half of this acreage existing as forests. Alarmingly, the annual losses have averaged 458,000 acres, an area about half the size of Rhode Island, of which 66% are forested. The most significant cause of this habitat destruction is the development of agriculture, which alone is responsible for 87% of all wetland degadation and 70% of the forested-wetland losses. In contrast, urban development accounts for only about 8% and 6% of the respective losses. It is concluded that there exists a pressing need for more intensive research and management of existing wetlands in order to maintain their current levels of fish and wildlife resources. dustrial expansion, residential development and ricultural activities have caused major changes forested-wetlands, significantly increasing their es of depletion. Data from the most recent forest rveys in the states of Virginia, North Carolina, uth Carolina, Georgia, and Florida were used to amine the wetland forest resources. Consistent imation of the forested wetland resource is diffit due to diverse species mixes and habitat types, ather cycles that influence hydroperiod, and the itrary timing of field visits. Using stand infortion collected on Forest Inventory and Analysis A) permanent plots, the area of wetland timberd in the southeastern United States was estimatand described. This method was comparable to classification method currently accepted by the A and the U.S. Army Corps of Engineers, ich routinely considers indicator species, soil a, and hydroperiod. Criteria also used in the A algorithm included overstory and understory cies occurrence, physiography, hydroperiod, cover type data. It was concluded that this is a sistent and repeatable method which is potenly useful for future wetland delineation and nagement. (Author's abstract)

At present, available information describing the impact of forestry activities on forested-wetland functions is insufficient for use in planning optimal management strategies. A methodology has been developed to assess the impact of timber-harvesting in a tidal freshwater palustrine wetland in southwestern Alabama. Biophysical as well as socio-economic parameters were examined to estimate both stand timber stocks and the extent of disruption of ecosystem functions. Specifically, indices were chosen to detect changes in net primary productivity, plant nutrient assimilative capacity, soil nutrient retention and transformation, decomposition, sedimentation rate, hydrology, and wildlife habitat provision. Furthermore, methods were chosen for data collection efficiency, interpretive simplicity, and the ability to provide a relative index of both the integrity and recovery rates of a disturbed ecosystem. This assessment enables wetland managers to determine which parameters are sensitive to functional changes, as well as the relative effects of various harvesting methods for use in promoting best forest management practices. The predicted global warming trend and resultant sea level rise will increase inundation and salinity along coastal regions worldwide. In addition, as water levels increase, saltwater will encroach farther inland in many areas. However, the resultant effects of these ecological changes on the major tree species of coastal forests are unknown. The present study, which evaluates tree-survival response to increased flooding and saltwater intrusion, demonstrates a substantial reduction of net photosynthesis in many bottomland hardwood and swamp-forest tree species on the U.S. Gulf Coast. The combination of flooding and salinity causes foliage damage and substantial reductions in carbon assimiliation. The morphological response and reductions in gas exchange rates are closely associated with increases in salt levels. Exposure to concentrations greater than 3 parts per thousand causes both leaf burning and decline (up to 84%) in carbon assimilation rates in seedlings, of some species. In addition, the sublethal stress can lead to weaker seedlings, and consequently, reduced survival rates of the susceptible species. (D'Agostino-PTT)

CAT ISLAND SWAMP: WINDOW TO A FADING LOUISIANA ECOLOGY.
Southern Forest Experiment Station, New Orleans, LA.
M. S. Devall.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 303-314, June 1990. 2 fig, 5 tab, 22 ref.

Descriptors: *Cat Island Swamp, *Forest ecosystems, *Land management, *Louisiana, *Swamps, *Wetland forests, Data acquisition, Ecological effects, Ecosystems, Species composition, Species diversity, Wetlands.

Currently, there is considerable awareness of the ecological importance of forested-wetlands, as well as an increasing concern over the long-term consequences of continued wetland losses. Future preservation of these habitats is predicated on understanding the topology of present swamp-forest communities, such as Cat Island swamp which borders the Mississippi River in Louisiana. In this tract, twenty species of trees were observed in six communities. Hadkberry (Celtis laevigata) had the highest importance value, followed by cypress (Taxodium distichum), green ash (Fraxinus pennsylvanica), and Tupelo gum (Nyssa aquatica). The understory was sparse, and saplings were not represented in the same frequency as mature trees. Of particular note is that no saplings of cypress, or of five other species, were present, suggesting an important future change in forest composition. Discriminant-function analysis indicated that of all the environmental variables considered, including soil conditions and nutrient status, changes due to human activities, such as lumbering, had the most significant influence on swamp tree survival and distribution. POSSIBLE EFFECTS OF RESIDENTIAL DEVELOPMENT ON STREAMFLOW, RIPARIAN PLANT COMMUNITIES, AND FISHERIES ON SMALL MOUNTAIN STREAMS IN CENTRAL ARIZONA.
Rocky Mountain Forest and Range Experiment Station, Tempe, AZ. Forestry Sciences Lab.
A. L. Medina.
Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 351-361, June 1990. 2 fig, 2 tab, 22 ref.

Descriptors: *Arizona, *Ecological effects, *Fisheries, *Forests, *Pine trees, *Regional development, *Streamflow, *Urbanization, Comparison studies, Ephemeral streams, Riparian vegetation.

Increased residential development along small mountain streams within the pine forests of central Arizona has surged within the last 20 years, presenting a potential threat to riparian plant communities due to the alteration of streamflow from perennial to ephemeral. This alteration significantly increases the water stress on plant populations. Measurements of tree densities and stand composition of Arizona alder (Alnus oblongifolia) and box elder (Acer negundo) showed that perennial stream reaches had greater tree densities in all diameter classes, compared with ephemeral stream reaches where small-diameter trees were absent. Xylem water potential measurements decreased more rapidly on trees occupying ephemeral stream reaches than on trees of comparable reaches of perennial streams over time during the summer. The increase in water stress in trees growing along ephemeral stream reaches may be responsible for both the lower plant densities and lack of seedling establishment observed. Trout populations also decline when perennial streamflow changed to ephemeral. (Author's abstract)

UTILITY OF STREAM HABITAT AND BIOTA FOR IDENTIFYING POTENTIAL CONFLICTING FOREST LAND USES: MONTANE RIPARIAN AREAS.
Rocky Mountain Forest and Range Experiment Station, Tempe, AZ. Forestry Sciences Lab.
J. N. Rinne.

Forest Ecology and Management FECMDW, Vol. 33/3, No. 1/4, p 363-383, June 1990. 6 fig, 91 ref.

Descriptors: *Forest ecosystems, *Forest watersheds, *Forests, *Land use, *Riparian vegetation, *Streams, *Wetlands, Data acquisition, Fish, Literature review, Macroinvertebrates, Particle size, Sediment distribution.

Since National Forest lands in the United States are managed through a multiple-resource approach, adopted practices often impose a conflict between two or more forest land uses. In addition, although many studies have assessed the impact of such land use practices on riparian stream areas, the practical usefulness of these approaches has not been clearly demonstrated. Through a review of the literature this study suggests the feasibility of using one physical feature of stream habitat, namely fine sediment, and two biological variables, aquatic macroinvertebrates and fish, to identify the effects of multiple use activities on riparian stream systems. Based on empirical data obtained from several southwestern montane streams, plus information derived from the existing literature, it was concluded that these three variables are valid indicators for detection of the effects of multiple use activities on riparian stream ecosystems. It was further concluded that multiple physical and biotic factors, such as solar radiation, water quality, water temperature, and type of vegetation, must also be considered for optimal management of the valuable forested wetlands. EDUCATED GUESSES: HEALTH RISK ASSESSMENT IN ENVIRONMENTAL IMPACT STATEMENTS.
P. D. Harvey.
American Journal of Law & Medicine AJLMDN, Vol. 16, No. 3, p 399-427, 1990. 185 ref.

Descriptors: *Environmental impact, *Environmental impact statement, *Environmental policy, *Environmental quality, *Public health, *Risk assessment, Administrative agencies, Environmental effects, Federal jurisdiction, Project planning, Regulations, Uncertainty.

Efforts to protect the environment and public health from environmental pollution begin with describing potential adverse consequences of human activities and characterizing the predicted risk. The National Environmental Policy Act (NEPA) requires the preparation of environmental impact statements (EIS) to describe the effects of proposed federal projects and provide information for agency decision makers and the public. The scope of the EIS requirement has been delineated by regulations and frequent lawsuits and covers all federal agencies planning any major project, including construction, ongoing management programs, provision of funds, and approval of permits needed by state and local governments or private businesses. In 1978, the Council on Environmental Quality (CEQ) promulgated regulations binding on all federal agencies to provide uniform standards for the implementation of NEPA. A worst case analysis requirement continues in importance as an historical perspective on approaches to the problem of inadequate information. In 1986, CEQ rejected the worst case analysis requirement and replaced it with more clearly articulated and manageable requirements. Agencies must still evaluate catastrophic/low probability consequences, and there was little change in the framework for EIS expression of uncertainties. The methodologies for risk assessment are complex and vulnerable to bias from underlying assumptions and policy judgements. Components of a risk assessment methodology may include dose-response assessment, population exposure assessment, and risk characterization. Recommendations for use of risk assessment in EIS include clear statement of assumptions and scientific judgements, delineation of the nature and magnitude of uncertainties, separation of risk assessment and risk management, explanation of the choice of methodology, presentation of risk estimates, and specification of the role of risk assessment in decision making. IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 605-621, 6 fig, 1 tab, 4 ref.

Descriptors: *Aquifer management, *England, *Environmental impact, *Gravel mining, *Groundwater management, *Groundwater resources, *Water resources management, Case studies, Databases, Finite difference methods, Geohydrology, Groundwater level, Groundwater movement, Groundwater quality, Groundwater recharge, Habitat restoration, Model studies, Monitoring, Surface-groundwater relations, Water quality.

Denge Beach, on the southeastern coastline of England, is an 'environmentally sensitive' area that is under increasing pressure from a combination of man-made and natural forces, including gravel extraction, water abstraction and storm surges. Recent hydrogeological studies were conducted to assess the impact of gravel extraction on the resources of the Denge gravel aquifer. A finite difference model, that incorporates the findings of extensive investigations over the past 10-15 years, has been constructed; complex boundary conditions and anisotropy are integrated into the model. A scheme has been developed to reduce groundwater discharge to surface water courses by restoring gravel workings at the edge of the aquifer with less permeable silt. Modeling indicates that this scheme will maintain and increase water levels in the aquifer, compared with those predicted for the original restoration proposals. The model may also be used as a baseline against which actual monitoring data can be checked and as an assessment of the progress of the scheme made as development proceeds. The large volume of monitoring data has made it possible to develop a model that can be tested against a large range of environmental and man-made factors. The interaction of wet mineral workings on aquifer storage, recharge, and water quality can only be assessed with confidence by the use of modeling techniques. The ever-increasing pressure on mineral extractors to reduce the environmental impact of their workings, coupled with developmental pressures that look for progressively deeper and often sub-watertable workings, is likely to increase the need for this type of study. ater samples were collected from the drainage stem of a Sitka spruce plantation at weekly inter-ls for six years. The drainage system had been signed to divide the plantation into a series of ificial catchments, three of which were designat-experimental plots and clearfelled in the second ar of sampling while a fourth was the control ot which remained unfelled until the end of the dy. Prior to felling, solute concentrations were ilar for all plots. Concentrations of nitrate, po-sium, and phosphate all rose following felling. trate concentrations peaked one year after the d of felling and returned to levels similar to the trol plot in the fourth year after felling. Potassi-and phosphate peaked in the second year after ing but had not returned to control levels by end of the study, although seasonal patterns become established, with lower concentrations summer. Concentrations of sulphate, sodium, chloride declined as a result of felling and ained lower than the control at the end of the dy. There was a very slight fall of pH and minum concentration after felling, relative to control. The three experimental plots behaved similar way for all ions except phosphate and which were released in greatest quantities the least intensively drained plot. (Author's tract)

sh Creek drains a 76.1 sq km watershed within n Kansas City, Missouri and eastern Kansas. A crete-lined reach trending 6.1 km through the a District of Kansas City, Missouri, has been Focus for several major floods over the past ten s. Channel geometry, slope, and floodwater ations were determined in the field for segments of the concrete-lined section of Brush Creek for a flood event that occurred on September 18, 1986. Discharge was computed by indirect methods and compared to a value determined from a rating curve established by the Water Resources Division of the U.S. Geological Survey. Boundary shear stress, unit stream power, and average velocity were also computed in order to establish a quantitative relationship between sediment distribution, volume, and size fractions; and flow dynamics operating throughout the channel during this event. Boundary shear stress ranged from 91-96 N/sq m, stream power was 528-557 W/sq m, while average velocity was 5.8 m/s. These values were sufficient to displace concrete slabs as large as 5 m long by 4.6 m wide by 0.23 m thick weighing an estimated 12,245 kg. As the channel was sediment-free and unscoured prior to the flood, the distribution of deposits and subsequent channel scour provide valuable evidence for potentially hazardous sections of this urban stream. The excavation of an extensive quarrying system in alluvial plains to supply building material may induce water table modifications that are not compatible with the natural environment or with the existing activities (e.g., agricultural or recreational) in the area. The hydrologic impact of a set of borrow pits designed to provide the material needed for the construction of an electro-nuclear plant at Trino Vercellese, northwestern Italy, was analyzed with the aid of a 3-D finite element model of subsurface flow. The results from the simulations show that a single quarry induces water-table changes that are considered to be unacceptable from the environmental point of view. Close to the excavation boundary, the water level can rise more than 1 m, with possible flooding of nearby areas. Also, outside the electro-nuclear plant property an increase or decrease of 0.2 m is considered to be significant. The results also show that the groundwater regime is not altered either transversely or longitudinally if the excavation volume is fractioned into six distinct cavities and the downstream wall of each cavity is made impermeable through the deposition of a layer of fine sediments or the application of a thin plastic foil. V. R. N. Chinene, D. Mbewe, and D. Lungu.
Tropical Agriculture TAGLA2, Vol. 67, No. 3, p 221-222, July 1990. 1 fig, 1 tab, 5 ref.

Descriptors: *Developing countries, *Erosion control, *Land use, *Soil erosion, Agriculture, Cowpeas, Crop yield, Groundnut, Millet, Productivity, Runoff, Zambia.

Erosion hazards in the Lusitu, Zambia area are one of the constraints limiting sustainable land productivity. Soil loss was measured using the runoff plot technique in five cropping systems (millet, bambara groundnuts, millet and bambara groundnuts, cowpeas, and millet and cowpeas) and a bare plot. Considerable variation in soil loss was apparent between different cropping systems. In the bare plot more than 12 tons soil per ha was lost. In millet and its intercrops, soil loss was nearly 50% lower than in the bare plot. Millet produced higher yields when intercropped with bambara groundnuts, and cowpea. Similarly, bambara groundnuts and cowpeas produced higher yields when intercropped with millet. Definite differences were demonstrated between cropping systems in controlling soil loss. Crop cover by itself has the capacity to reduce soil loss by nearly 50%. Crops such as bambara groundnuts and cowpeas which develop small leaf canopies should only be grown as intercrops to minimize soil loss and optimize productivity. (Brunone-PTT)

Descriptors: *Bioindicators, *Cuba, *Echinoderms, *Heavy metals, *Marine pollution, *Path of pollutants, *Statistical analysis, Analysis of variance, Cluster analysis, Copper, Data interpretation, Havana, Iron, Manganese, Mercury, Pollutant identification, Tissue analysis, Water quality, Zinc.

Between March 1986 and June 1987, the content of iron, zinc and manganese in the hard parts, and the content of iron, copper, zinc and mercury in the gonads, of the sea urchin Echinometra Iucunter were studied. The specimens were collected from sites on the rocky shore of Havana, Cuba, which had different levels of heavy metal pollution. The sampling sites were Santa Cruz, Rincon de Guanabo, Alamar, Boca de la Bahia, Nautico and Santa Fe. Differences were found in the metal content of both the gonads and the hard parts. These differences were explained by the triglyceride content of the gonads and the higher organic content of the gonads, (> 90%), compared with 13% for the hard parts. The results were processed by analysis of variance (ANOVA) and cluster analysis. Seasonal variations were found by ANOVA. The differences between the sites that had been studied indicate that the gonads can act as an indicator of iron and mercury pollution and the hard parts as an indicator of iron, zinc and manganese pollution. Zeitschrift fuer Wasser - und Abwasser Forschung ZWABAQ, Vol. 23, No. 3, p 98-101, June 1990. 4 fig, 4 tab, 3 ref. English summary.

Descriptors: *Analytical techniques, *Laboratory methods, *Pesticides, *Toxicity, *Wastewater analysis, *Water analysis, Aldehyde dehydrogenase, Captafol, Dithiocarbamates, Fentinacetate, Maneb, Water quality.

Based on the inhibition of aldehyde dehydrogenase by pesticides, an enzymatic toxicity test is presented for testing water and wastewater. The test protocols are given for photometric measurement in cuvets and fluorometric measurement in microtiter plates. Using microtiter plates minimizes the costs by saving expensive reagents, and enables the testing of a higher quality of samples by rapid measurement of dilution series. The results of 17 tested pesticides are described: the dose-response curves of Maneb, Captafol and Fentinacetate are shown as examples. Dithiocarbamates inhibit aldehyde dehydrogenase in a low ppt range. The test in microtiter wells is more sensitive because of the lower concentration of substrate, enzyme and coenzyme in molecular rate. (Author's abstract)

COASTAL WATER POLLUTION: DISSOLVED HEAVY METALS AND SUSPENDED PARTICULATE MATTER.
Patras Univ. (Greece).
A. Koliadima, and G. Karaiskakis.
Zeitschrift fuer Wasser - und Abwasser Forschung ZWABAQ, Vol. 23, No. 3, p 102-105, June 1990. 2 fig, 6 tab, 10 ref. International Atomic Energy Agency Contract 4621/EP.

Descriptors: *Greece, *Heavy metals, *Path of pollutants, *Pollutant identification, *Water pollution sources, Cadmium, Copper, Lead, Marine pollution, Particle size, Patras, Photosedimentation, Polarographic analysis, Suspended sediments, Water quality, Zinc.

Concentrations of the heavy metals, Zn, Cd, Pb, and Cu dissolved in coastal water samples collected from around the city of Patras, were measured over a period of one year, with a frequency of one sample per month, by polarographic methods. Lower annual mean concentrations of dissolved Zn and Cu were found in coastal locations close to the mouths of rivers, while the annual mean concentrations of dissolved Cd and Pb were found to be independent of the sampling location. The mean number diameter of the suspended particulate matter, as measured by photosedimentation, was found to increase with a decrease in the concentration of dissolved Zn, as well as an increase in the concentration of the dissolved Cu. (Author's abstract)

M. J. Morgan, L. L. Fancey, and J. W. Kiceniuk.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 9, p 1652-1654, September 1990. 1 tab, 20 ref.

Descriptors: *Acetylcholinesterase, *Bioindicators, *Fenitrothion, *Fish physiology, *Insecticides, *Pesticides, *Salmon, *Water pollution effects, Enzyme activity, Marine pollution, Metabolism, Organophosphorus pesticides, Pesticide toxicity.

Exposure to organophosphorus insecticides is known to decrease the activity of brain acetylcholinesterase, and a 20% decrease in the enzyme's activity relative to controls is taken as evidence that animals have been in contact with an organophosphorus pesticide. Atlantic salmon (Salmo salar) parr were exposed to a number of concentrations of either technical grade fenitrothion or an operational formulation of the pesticide for 7 days or to the operational formulation for two, 24 hour periods separated by seven days. Brain acetylcholinesterase (AChE) activity decreased as concentration of fenitrothion increased. Recovery period was directly related to amount of depression, with recovery of AChE from exposure to 0.004 microl/L fenitrothion taking less than one week. Samples must be taken soon after spray operation to detect exposure to such low levels of fenitrothion through AChE monitoring. The use of AChE activity measurements as a monitoring tool in aquatic systems should reliably detect exposure to dangerous levels of fenitrothion which might produce significant population changes. (Brunone-PTT)

PRECONCENTRATION OF COPPER ON ALGAE AND DETERMINATION BY SLURRY GRAPHITE FURNACE ATOMIC ABSORPTION SPECTROMETRY.
Texas Univ. at Austin. Dept. of Chemistry and Biochemistry.
M. Shengjun, and J. A. Holcombe.
Analytical Chemistry ANCHAM, Vol. 62, No. 18, p 1994-1997, September 15, 1990. 4 fig, 4 tab, 8 ref.
Robert A. Welch Foundation Grant F1108.

Descriptors: *Atomic absorption spectrophotometry, *Chemical analysis, *Chlorella, *Copper, *Laboratory methods, *Pollutant identification, *Preconcentration, *Water analysis, *Water treatment, Adsorption, Freshwater, Heavy metals, Hydrogen ion concentration, Seawater.

Unicellular green algae (Chlorella) were utilized to preconcentrate Cu ions from seawater and riverine water samples. Studies show that after the algae are rinsed with 1% HCl, Cu adsorption on the algae is improved. The addition of sodium citrate and dodecyl sulfate can also improve Cu adsorption. The algae weight and the solution pH are not critical. The seawater matrix does not affect the adsorption efficiency for Cu. Cu preconcentration can be achieved by mixing 6 mg of algae with 100 ml of sample and subsequently separating by centrifugation. The algae pellet is then resuspended in 1 ml of 0.5% HNO3 and analyzed as a slurry by graphite furnace atomic adsorption spectrometry. The determined values of Cu in riverine (SLRS-1) and seawater (CASS-1) standard reference materials are within the limits of certification. (Author abstract)

ENZYME-LINKED IMMUNOSORBENT ASSAY COMPARED WITH GAS CHROMATOGRAPHY/MASS SPECTROMETRY FOR THE DETERMINATION OF TRIAZINE HERBICIDES IN WATER.
Geological Survey, Lawrence, KS. Water Resources Div.
E. M. Thurman, M. Meyer, M. Pomes, C. A. Perry, and A. P. Schwab.
Analytical Chemistry ANCHAM, Vol. 62, No. 1, p 2043-2048, September 15, 1990. 4 fig, 4 tab, 2 ref.

Descriptors: *Chemical analysis, *Gas chromatography, *Herbicides, *Immunoassay, *Laboratory methods, *Mass spectrometry, *Pollutant identi

tion, *Triazine herbicides, *Triazines, *Water alysis, Comparison studies, ELISA, Enzymes, etabolites, Organic compounds.

n enzyme-linked immunosorbent assay (ELISA) as compared to a gas chromatography/mass ectrometry (GC/MS) procedure for the analysis triazine herbicides and their metabolites in sur- e water and groundwater. Apparent recoveries m natural water and spiked water by both meth- s were comparable at 0.2-2 micrograms/L. lid-phase extraction (SPE) was examined also, d recoveries were determined for a suite of zine herbicides. A significant correlation was ained between the ELISA and GC/MS method natural water samples that were extracted by E. Because ELISA was developed with an atra- e-like compound as the hapten with conjugation he 2-position, it was selective for triazines that tained both ethyl and isopropyl side chains. ncentrations for 50% inhibition (IC50) were as ows: atrazine, 0.4 micrograms/L; ametryne, 5 micrograms/L; prometryn and propazine, 0.5 rograms/L; prometon, 0.7 micrograms/L; si- zine and terbutryn, 2.5 micrograms/L; hydrox- razine, 28 micrograms/L; deethylatrazine and sopropylatrazine, 30 micrograms/L; cyanazine, micrograms/L; didealkylatrazine had no re- nse. The combination of screening analysis by ISA, which requires no sample preparation and rks on 160 microliters of sample, and confirma- by GC/MS was designed for rapid, inexpen- analysis of triazine herbicides in water. HODS FOR ASSESSING FERTILIZATION EMBRYONIC/LARVAL DEVELOPMENT OXICITY TESTS USING THE CALIFOR- MUSSEL (MYTILUS CALIFORNIANUS).
rnia Univ., Bodega Bay. Bodega Marine

Cherr, J. Shoffner-McGee, and J. M. er.
onmental Toxicology and Chemistry CDK, Vol. 9, No. 9, p 1137-1145, September 1990. 9 fig, 2 tab, 20 ref.

Descriptors: *Analytical methods, *Bioassay, *Bioindicators, *Embryonic growth stage, *Mytilus, *Toxicity, *Toxicology, DNA, Fertilization, Fluorescence, Larvae, Microscopy, Mussels, Polarization, Pollutant identification.

The fertilized eggs, embryos and larvae of the California mussel (Mytilus californianus) were used to develop methods for assessing fertilization and larval development rates, and for conducting toxicity tests in standard exposure chambers and small volume (3 ml) chambers. Because the sperm/egg ratio resulting in high monospermic fertilization rates varied among females, the 'optimal' ratio for each female was predetermined in an aliquot of eggs prior to fertilizing the entire batch for bioassay use. The fluorescent DNA probe Hoechst 33342 was used to rapidly differentiate unfertilized, monospermic and polyspermic eggs. Following fertilization of entire batches of eggs based on the predetermined sperm/egg ratio, monospermic fertilization rates of >90% were readily achieved. Fertilized embryos were then used in bioassays conducted in beakers of tissue-culture chamber slides (mini chambers), which could be viewed directly on the microscope. The response of the embryos and larvae to the metabolic inhibitor sodium azide was assessed in both types of test chambers. At 96 h postinsemination at 12 degrees, veliger or nonveliger larvae were assessed using polarization microscopy to determine the presence or absence of a complete shell. No significant difference in the response to sodium azide was detected between the beakers and mini chambers. M. californianus is suitable for static embryo/larval toxicity tests, and small volume chambers allow successful larval development and eliminate the need for subsampling of larger test chambers. The value of assessing fertilization rates prior to conducting the bioassay, and an improved method for examining larval shell development using polarization microscopy were demonstrated. RAINBOW TROUT LIVER ACTIVATION SYSTEMS WITH THE AMES MUTAGENICITY TEST.
National Fisheries Contaminant Research Center, Columbia, MO.
B. T. Johnson.
Environmental Toxicology and Chemistry ETOCDK, Vol. 9, No. 9, p 1183-1192, September 1990. 3 fig, 6 tab, 41 ref.

Descriptors: *Ames test, *Genotoxicity, *Liver, *Mutagenicity, *Pollutant identification, *Toxicology, *Trout, Animal metabolism, Bioassay, Cytochromes, Enzymes, Laboratory methods, Metabolites, Mutagens, Salmonella, Temperature effects.

A poikilothermic metabolic activation system developed from liver homogenate of rainbow trout (Oncorhynchus mykiss, formerly Salmo gairdneri) was used in the Ames Salmonella/Mammalian Microsome Mutagenicity Test. Postmitochondrial fractions (S9) mediated four model promutagens: 2-aminoanthracene (2AA), 2-aminofluorene (2AF), benzo(alpha)pyrene (BaP), and 3-methylcholanthrene (3MC). These promutagens require two different exogenous metabolic activation routes to form mutagens with Salmonella TA98 and TA100. The enzymatic activity of trout S9 was cytochrome P-450-like; it was heat labile and oxygen-dependent and cofactor-dependent. Preincubation temperature significantly influenced the sensitivity of the fish-activated Ames test. Bacterial mutagenesis with trout activation significantly decreased as preincubation temperature increased; the optimum S9 activation temperature range for trout was 10 to 15 degrees compared with 37 degrees for the rat. The liquid-preincubation test was best adapted to the trout poikilothermic activation system; it was significantly more sensitive than the plate-incorporation test in detecting histidine revertants. The S9 activity of trout and rat was qualitatively similar in the Ames test; that is, both fractions metabolically activated 2AA, 2AF, BaP and 3MC to produce bacterial mutagenesis with Salmonella TA98 and TA100. The use of this ecologically relevant exogenous activation system in the short-term predictive genotoxicity testing of freshwater ecosystems is helpful in the assessment of potential hazards of chemical contaminants on fishery resources. COMPARATIVE EVALUATION OF FIVE TOXICITY TESTS WITH SEDIMENTS FROM SAN FRANCISCO BAY AND TOMALES BAY, CALIFORNIA.
National Ocean Service, Seattle, WA. Ocean Assessments Div.
E. R. Long, M. F. Buchman, S. M. Bay, R. J. Breteler, and R. S. Carr.
Environmental Toxicology and Chemistry ETOCDK, Vol. 9, No. 9, p 1193-1214, September 1990. 13 tab, 38 ref.

Descriptors: *Mutagenicity, *San Francisco Bay, *Sediment contamination, *Toxicity, *Toxicology, *Water pollution effects, Amphipods, Chemical analysis, Coastal environment, Comparison studies, Echinoderms, Embryonic growth stage, Genotoxicity, Hydrocarbons, Marine environment, Mussels, Mytilus, Organic carbon, Pollutant identification, Polychaetes, Sediment analysis, Trace metals.

The relative sensitivity, analytical precision, discriminatory power and concordance among endpoints with sediment chemistry were compared among five sediment toxicity tests. The tests were performed with aliquots of 15 composited, homogenized sediment samples. Survival and a variety of sublethal endpoints were determined in tests performed with the amphipods Rhepoxynius abronius and Ampelisca abdita, embryos of the mussel Mytilus edulis, embryos of the urchin Strongylocentrotus purpuratus and the polychaete Dinophilus gyrociliatus. Each sample was also tested for trace metal and organic compound concentrations, organic carbon content and texture. Two of the five tests (survival among M. edulis and survival among R. abronius) were highly sensitive to the samples and had relatively high precision, but the results were correlated most highly with sedimentological variables. One of the tests (survival among A. abdita) was relatively insensitive, but the results were highly correlated with only the concentrations of toxic chemicals. The test with S. purpuratus indicated mutagenicity in several samples that had high hydrocarbon concentrations. The test of pore water with D. gyrociliatus was intermediate in sensitivity and precision and not correlated highly with the results from other tests. (Author's abstract)

COMPARISON OF QUARTER-HOURLY ON-LINE DYNAMIC HEADSPACE ANALYSIS TO PURGE-AND-TRAP ANALYSIS OF VARYING VOLATILE ORGANIC COMPOUNDS IN DRINKING WATER SOURCES.
Drexel Univ., Philadelphia, PA. Dept. of Chemistry.
J. G. Schnable, B. Dussert, I. H. Suffet, and C. D. Hertz.
Journal of Chromatography JOCRAM, Vol. 513, p 47-54, July 27, 1990. 6 fig, 1 tab, 7 ref.

Descriptors: *Analytical methods, *Monitoring, *Pollutant identification, *Volatile organic compounds, *Water supply, Chemical analysis, Comparison studies, Electronic equipment, Gas chromatography, Water conveyance.

The temporal monitoring of volatile organic compounds (VOCs) in water sources is important be-

cause of contamination and the transport of contaminants. This project was the first application of quarter-hourly on-line headspace analysis for monitoring VOC concentrations in surface and ground waters, for extended periods of time. A Siemens P101 dynamic headspace analyzer was refined, and quality assurance was developed for quarter-hourly analyses. Hourly comparisons were made to on-line purge-and-trap analysis and to purge-and-trap analysis after sample preservation and storage. Variations in VOC concentrations of 6047% biweekly, 222% daily, 97% hourly, and 35% quarter-hourly were observable, with the 15-min cycle of the dynamic headspace analysis. The headspace analyzer had superior retention time stability, required less maintenance, and had 1/4 the analysis time as a typical purge-and-trap-gas chromatography system used for hourly comparisons. PERIPHYTON AS INDICATOR OF THE RESERVOIR WATER QUALITY: III. BIOMONITORING TECHNIQUES.
Prague Dept. of Water Technology and Environmental Engineering (Czechoslovakia).
A. Sladeckova.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 775-782, 1990. 2 fig, 30 ref.

Descriptors: *Analytical methods, *Bioassay, *Bioindicators, *Limnology, *Monitoring, *Periphyton, *Reservoirs, *Water quality, Algae, Ciliates, Diatoms, Organic compounds, Protozoa, Trace metals.

Periphyton bioassays on species, community, and microcosm levels conducted in situ or in the laboratory using field-collected water can be used for the biomonitoring of pollution, eutrophication, and toxic effects of the water quality of reservoirs and their tributaries. Such assays measure important environmental stress factors in natural localities. (1) On the species level, the algae Stigeoclonium subsecundum and Cladophora glomerata and the ciliate Vorticella convallaria have been shown to be good biological monitors of water pollution. (2) On the community level, diatoms have been used as representatives of the algal components of the periphyton community, mostly for the monitoring of organic pollution, nutrient enrichment, and bioaccumulation of trace metals. Protozoan community structure and colonization dynamics have also been used for testing water pollutants. The majority of procedures using the entire periphyton community to monitor water quality are based on the exposure of artificial substrates. The aim is to provide comparable conditions for periphyton colonization in localities with variable or nonexistent natural substrata. (3) At the microcosm level, experimental units are used to contain important components and to exhibit important processes occurring in a whole ecosystem. Designed mostly for simulating the conditions in flowing water, they are also appropriate for testing water quality in reservoir tributaries. The choice of an appropriate bioassay technique or of the best combination of several methods will be dictated by the specific data requirements of the study, by the level of environmental control desired and by the investigator's resources and equipment. Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 861-867, 1990. 1 fig, 3 tab, 4 ref.

Descriptors: *Algae, *Bacteria, *Bioassay, *Pollution index, *Reservoirs, *Water quality, Chlamydomonas, Czechoslovakia, Escherichia coli, Nitrates, Phosphates, Scenedesmus, Serratia.

In evaluating the water quality of reservoirs, in addition to physical and chemical analyses biological methods have become increasingly important. Several biological procedures were used in a study of the water quality of six Czechoslovakian reservoirs. The results were compared with physical and chemical data to determine the water quality at the chosen localities and to evaluate the results obtained from the methodological points of view and the importance of individual factors which affect the water quality. The ecological procedures included saprobity zones determination, based on biological analyses, and determination of total numbers of bacteria multiplying at 37 C and 20 C and the number of coliforms. Experimental biological procedures (physiological tests) included bioassays with algae (Scenedesmus quadricauda and Chlamydomonas eugametos) and bioassays with bacteria (Escherichia coli and Serratia marcescens). The following results were obtained: (1) the physiological tests with both algae species had a very similar course; (2) the results with both algae depended on the contents of phosphates in the samples examined; (3) phosphorus was proved as the limiting factor at the investigated localities; (4) the results of the physiological tests with algae were not closely related to the contents of nitrates in the samples; (5) the mutual relationship between the results of bioassays with algae and bacteria was not significant; (6) the results of the physiological tests with both bacteria were very similar and were in good conformity with the contents of nitrates; (7) the saprobic index according to Sladecek at the investigated localities compared with the chemical and physical data, and the results of physiological tests applied varied less. Because of concerns about viruses and other microbial contaminants in drinking water, the US EPA recently promulgated the Surface Water Treatment Rule, which requires filtration and disinfection to achieve a 99.99% virus reduction. A groundwater disinfection rule targeted at controlling viruses and other microbial pathogens through disinfection is now in preparation. The development of treatment requirements to control viruses in drinking water is based, in part, on the inability to define a practical virus standard or develop a technically feasible, reliable, inexpensive, and rapid virus monitoring strategy or virus indicator system. Recent research suggests that male-specific (F-specific) RNA coliphages, a group of small, icosahedral bacteriophages infecting male strains of Escherichia coli, may fulfill many of the essential requirements of a viral indicator. A simpl membrane filter method for concentrating and enu merating F-specific coliphages in raw and finishe drinking water was developed with a view to usin these phages as a viral indicator. F-specific col phages were enumerated by plaque assays on specially constructed host of Salmonella typhimu ium that is resistant to nalidixic acid and kanam cin and contains an E. coli plasmid responsible fo E. coli pili production and, thus, susceptibility infection by F-specific coliphages. The metho developed was field-tested by determining the co centrations of F-specific coliphages in sever source waters and comparing them with concen trations of fecal indicator bacteria. The resul suggest that the new membrane filter method fo enumerating F-specific coliphages should be usef for assessing fecal contamination of natural an treated waters. Additional studies are needed determine whether these coliphages are reliab indicators of enteric viruses in water. (Mertz-PTT

Descriptors: *Analytical techniques, *Chemi analysis, *High performance liquid chromatogr phy, *Liquid chromatography, *Mass spectrom try, *Organic compounds, *Pollutant identifi tion, *Water analysis, Detection limits, Drinki water, Particle beam, Regulations, Separation tec niques.

Most currently regulated organic compoun found in drinking water are amenable to separati and measurement by gas chromatography. A n generation of compounds being proposed for re lation includes some that are not amenable to se ration and measurement with this technique. T emerging analytical technology of liquid chrom tography-mass spectometry is considered a lik candidate for the separation and measurement nonvolatile compounds in drinking water. Hi pressure liquid chromatography-particle-bea mass spectrometry shows promise as broad-sp trum analytical technique applicable to the det mination of a variety of nonvolatile compounds drinking water and other environmental samp The combination of precise retention times, el tron ionization mass spectra, and isotope distri tion patterns from compounds containing natura occurring isotopes gives excellent information the unequivocal identification of target and un pected analytes. The precision, calibration, instrument detection limits obtained with h pressure liquid chromatography-particle-bea mass spectrometry are encouraging and sugg that it will be possible to develop a broad-spectr analytical method. Particle-beam liquid chro tography-mass spectrometry technology is r tively new, and substantial improvements in tems and performance are expected during early 1990s. (Mertz-PTT)

/ater Treatment Rule, Water quality control, /ater quality standards, Zinc sulfate method.

pidemiological studies have shown that Giardia mblia is widespread, with infection rates among dividuals in North America ranging from 1.5-%. Giardia has been reported to be present in -28% of lakes, rivers, and creeks tested. The ccidian protozoan, Cryptosporidium, was not cognized in humans until 1976. In recent years s parasite has been isolated in stools at a rate of to 23%. Cryptosporidium appears to be widely tributed in the aquatic environment. An immun-uorescence method for the simultaneous detec-n of Giardia and Cryptosporidium in water was mpared with the zinc sulfate flotation and gol's iodine method in surface water samples lected in western Pennsylvania. The results owed that the immunofluorescence technique ected approximately 12 times more Giardia ts in surface water samples than the zinc sulfate thod. In addition, Cryptosporidium was detect-in several samples. Application of the immuno-orescence procedure for surface waters detected rdia at levels as high as 690 cysts/100 gallon at level, utilization of the 99% filtration criteria posed in the Surface Water Treatment Rule ld still result in about 7 Giardia cysts/100 on of filtered water. The results are significant use they represent levels not detected using zinc sulfate flotation technique. These data gest that operators of treatment plants with r source-water quality should pay special atten-to flocculation, coagulation, and filtration esses to optimize parasite removal. (Mertz-)

ITY TEST PROCEDURES FOR HYA-AZTECA, AND CHRONIC TOXICITY CADMIUM AND PENTACHLORO-OL TO H. AZTECA, GAMMARUS FAS-S, AND DAPHNIA MAGNA.
Department of Fisheries and Oceans, Burlington (Ontario). Great Lakes Lab. for Fisheries and Aquatic Sciences.
U. Borgmann, K. M. Ralph, and W. P. Norwood.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 18, No. 5, p 756-764, September 1989. 4 fig, 6 tab, 34 ref.

Descriptors: *Amphipods, *Bioindicators, *Cadmium, *Chronic toxicity, *Pentachlorophenol, *Toxicity, *Toxicology, *Water pollution effects, *Waterfleas, Aquatic animals, Aquatic environment, Benthic environment, Cultures, Culturing techniques, Daphnia, Gammarus, Great Lakes, Growth, Hyalella, Life cycles, Mortality, Substrates, Survival.

Survival, growth, and reproduction of Hyalella azteca were determined under various test conditions. Reproduction by a cohort begins when the amphipods are 5 to 6 weeks old, peaks at 8 to 12 weeks, and then declines due to continuing adult mortality. Full life-cycle tests can be completed in 12 to 14 weeks at 25 C. Reproduction is poor when only artificial plastic substrate is provided. A substrate of cotton gauge results in dramatic improvements in both reproduction and growth. Better reproduction can be obtained by culturing the amphipods in some sediments, but this makes weekly enumeration difficult. Increased mortality during chronic exposure to cadmium was observed at 1 microgram/L for H. azteca and 3.2 microgram/L for Gammarus fasciatus. Reproduction during longer exposure was not reduced at concentrations lower than those causing increased mortality within six weeks. Chronic toxicity of pentachlorophenol was observed at 100 micrograms/L for both species. Chronic toxicity to Daphnia magna was similar to that of the amphipods for cadmium, but lower for pentachlorophenol. Amphipods are at least as sensitive as Daphnia to a variety of toxicants during chronic exposure. (Author's abstract)

Descriptors: *Analytical methods, *Drinking water, *Immunoassay, *Pesticides, *Pollutant identification, *Water analysis, Antibodies, Atrazine, Detection limits, Organic solvents, Propazine, Simazine, Toluene, Triazine herbicides.

Preconcentration of pesticides in drinking water by extraction or elution from columns with organic solvents has been used to improve detection limits in various analytical methods. To assess the applicability of preconcentration in organic solvents to immunochemical techniques, the binding of atrazine and an atrazine derivative dissolved in various nonpolar organic solvents to immobilized polyclonal antibodies was studied. The antibodies immobilized onto immunodyne membranes were stable in chloroform and in buffer for at least 65 h at room temperature. The apparent binding affinity was lower in the five solvents tested than in buffer, and showed a correlation with the polarities of the solvents and with the solubilities of the haptens in the solvents. An increase in the antibody-hapten binding specificity by the use of toluene as the solvent for atrazine, propazine and simazine was observed. (Mackeen-PTT)

DETERMINATION OF COBALT BY ADSORPTIVE STRIPPING VOLTAMMETRY USING COBALT(II)-NIOXIME-NITRITE CATALYTIC SYSTEM.
Academy of Mining and Metallurgy, Krakow (Poland). Inst. of Material Science.
A. Bobrowski.
Analytical Letters ANALBP, Vol. 23, No. 8, p 1487-1503, August 1990. 4 fig, 1 tab, 35 ref.

Descriptors: *Analytical methods, *Cobalt, *Pollutant identification, *Water analysis, Adsorption, Detection limits, Drinking water, Natural waters, Nickel, Voltammetry, Water pollution, Water sampling, Zinc.

A differential pulse adsorptive voltammetric method was developed for cobalt determination with a detection limit of 120 pM (100 sec preconcentration). The preconcentration of Co(II)-nioxime complex during the adsorption step and the utilization of catalytic effect during the reduction of Co(II)-nioxime complex provide great enhancement of cobalt voltammetric response. The ammonia buffer solution containing nioxime and nitrite is suitable for the adsorptive voltammetric determination of nanomolar cobalt concentrations in the presence of 1000-fold excess of nickel and 10,000-fold excess of zinc. The sensitivity and selectivity of the proposed method are significantly higher than those of the well-known adsorptive voltammetric method with dimethylglyoxime. The method has been tested for the determination of Co in river, canal and tap water samples. (Author's abstract)

ANALYTICAL PROPERTIES OF 4,4'-BIAZOBENZENEDIAZOAMINOBENZENE AND ITS APPLICATIONS IN SPECTROPHOTOMETRY.
China National Environmental Monitoring Centre, Beijing.
F. Wei, W. Jiang, E. Teng, Y. Zhu, and J. Liu.
Analytical Letters ANALBP, Vol. 23, No. 7, p 1181-1190, July 1990. 4 fig, 3 tab, 7 ref.

Descriptors: *Azo dyes, *Chelating agents, *Chemical analysis, *Colorimetry, *Heavy metals, *Metal complexes, *Pollutant identification, *Spectrophotometry, *Water analysis, Analytical methods, Cadmium, Chemical properties, Reagents, Water pollution.

In the past, chelating ligands with auxochromic groups at the para-position of benzenediazoaminoazobenzene have been studied as agents for the spectrophotometric determination of transition metal ions. In this study, 4,4'-biazobenzene diazoamino benzene was synthesized from para-aminoazobenzene reacted in nitroso-sulfuric acid medium. Due to the existence of a strong auxochromic group (p-benzeneazo) in the molecule, the reagent has intense color reactions with some transition metal ions. The reagent is insoluble in water, soluble in organic solvents such as acetone, chloroform, benzene, carbon tetrachloride, and ethanol. In neutral and alkaline media, the reagent solution is yellow and stable for at least a month. In the presence of Triton X-100 and sodium tetraborate solution, the reagent reacted with mercury(II), nickel(II), cadmium(II), copper(II), zinc(II), cobalt(II), palladium(II) and silver(I) to form stable, highly sensitive complexes, exhibiting a red

color. Other metal ions were complexed, but these did not generate a detectable color. Molar absorptivities were 180,000 L/mol/cm at 515 nm for mercury, 200,000 L/mol/cm at 540 nm for nickel, and 180,000 L/mol/cm at 526 nm for cadmium. The reagent was used for spectrophotometric determination of cadmium in industrial waste waters from a smelter, battery works, and an alkali works. Results agree well with those of atomic absorption spectrophotometry. Interference from other metal ions can be eliminated by extraction separation. (VerNooy-PTT)

3-Chloro-4-(dichloromethyl)-5-hydroxy-2(5H)-furanone (MX) is the most potent member of a family of genotoxins resulting from the disinfection of drinking water and the bleaching of wood pulp by chlorination. MX is often a major contributor to the mutagenic activity of drinking waters. It as a direct-acting bacterial mutagen and a mammalian cell clastogen and forms an adduct with DNA. Unexpectedly, crystals of an MX anhydride were formed, in the course of unsuccessful attempts to obtain MX in a form appropriate for X-ray crystallography. A crude sample of MX was flash-chromatographed twice and the colorless oil obtained stored at -18 C for 6 months. The resulting crystalline solid was recrystallized from n-hexane-ether at room temperature. Crystals were examined by thin layer chromatography, infrared analysis, and (1)H NMR (nuclear magnetic resonance). From a computer-generated perspective drawing of the final X-ray model (one enantiomer of the racemic mixture), comparison of the anomeric torsion angles revealed that the crystal lacked the expected molecular of a dl diastereomer. A space-filling molecular model of the X-ray structure illustrated there is essentially an oxygen-dominated surface, and an opposite, chlorine-dominated surface. There is little doubt that MX's genotoxicity is a manifestation of the compound's electrophilicity; each of the five carbons is an electrophilic site. The anhydride's structure information anticipates a mode of reactivity that could account for MX's mutagenic potency. (VerNooy-PTT)

ANALYTICAL APPROACH TO ASSESSMENT OF LONG-TERM EFFECTS OF LOW LEVELS OF CONTAMINANTS IN THE MARINE ENVIRONMENT.
Cambridge Univ. (England). Dept. of Zoology.
G. Howells, D. Calamari, J. Gray, and P. G. Wells.
Marine Pollution Bulletin MPNBAZ, Vol. 21, No. 8, p 371-375, August 1990. 1 fig, 3 tab.

Descriptors: *Chronic toxicity, *Coastal waters, *Environmental effects, *Hazard assessment, *Marine pollution, *Monitoring, *Pollutant identification, *Water pollution effects, Baseline studies, Case studies, Indicators, Long-term planning, Marine environment, Pollutants, Water pollution control.

Detection of long-term changes due to low level contamination in the coastal and inshore marine environment is very difficult, both because of the complexity and interactive nature of ecosystems, of their variability in time and space, and the absence in most situations of a norm or baseline representing the pristine, or even the previous state of a particular ecosystem or community. There is also the problem of identifying the nature and source of contamination and the type of exposure. An analytical approach to assessment is proposed and its validity tested by reference to a few cases where there is judged to be strong evidence of biological change in response to a persistent but low level of contamination. A few examples of contaminants have been identified and selected, including nutrients, chlorinated hydrocarbons, tributyl tin, and hydrocarbons. In these four examples there is a sufficient body of quantitative and qualitative data where the cause of damage is indisputable and where the agent is present in low and persistent concentrations. They represent a diversity of causal agents and of biological responses, i.e., primary productivity, reproduction, growth and non-specific biological responses. These examples illustrate the kinds of information needed for assessment leading to control and monitoring, and where early warning signals can be identified and included in a monitoring program. A major challenge is to be able to document contaminant induced change against the highly variable and complex pattern of natural conditions. A second challenge is to detect change in an imperfectly understood marine ecosystem. In addition, improvement and calibration of ecotoxicological methods for detecting chemically inducted changes is needed. A detailed evaluation of a wider range of data to substantiate and verify the thesis that long-term biological changes can be attributed to low-levels of contamination is also required. (VerNooy-PTT)

FUCUS VESICULOSUS AS AN INDICATOR OF HEAVY METAL AVAILABILITY IN A FISH FARM RECIPIENT IN THE NORTHERN BALTIC SEA.
Abo Akademi, Turku (Finland). Dept. of Biology.
O. Ronnberg, K. Adjers, C. Ruokolahti, and M. Bondestam.
Marine Pollution Bulletin MPNBAZ, Vol. 21, No. 8, p 388-392, August 1990. 5 fig, 20 ref.

Descriptors: *Algae, *Baltic Sea, *Bioindicators, *Coastal waters, *Finland, *Fish farming, *Fucus, *Heavy metals, *Path of pollutants, *Water pollution sources, Aquaculture, Copper, Iron, Manganese, Marine pollution, Seasonal variation, Trout, Zinc.

In recent years, cage farming of rainbow trout has been a strongly expanding industry in Finnish coastal waters, with 1988 production exceeding 12,700 tons. Contents of zinc (Zn), manganese (Mn), and copper (Cu) in the brown seaweed Fucus vesiculosus L. were studied between May 1987 and April 1988 near a fish farm in the Aland archipelago, southwest Finland. Measurements were made on samples from naturally growing Fucus specimens from an unaffected reference locality and from specimens transplanted to the vicinity of the farm (50, 200 and 700 m away). At the unaffected locality there was a clear seasonal variation in contents of the studied metals in growing tips of Fucus specimens. Significantly higher content of Fe and Cu were measured in autumn and winter in specimens transplanted close to the farm. In summer, the contents of Mn and Zn showed an increasing tendency with decreasing distance to the farm. Results indicate marked seasonal variations in metal contents and the applicability of Fucus vesiculosus as an indicator of the availability of Zn, Mn and Cu in fish farm recipients in the Baltic Sea. The irregular variation in the concentration of iron makes Fucus less useable as an indicator of iron availability. (VerNooy-PTT)

GUIDELINES FOR PHYSICAL AND BIOLOG CAL MONITORING OF AQUATIC DREDGE MATERIAL DISPOSAL SITES.
Army Engineer Waterways Experiment Stati Vicksburg, MS. Environmental Lab.
T. J. Fredette, D. A. Nelson, J. E. Clausner, and J. Anders.
Available from the National Technical Informat Service, Springfield, VA 22161. Technical Rep No. D-90-12. September, 1990. 46 p, 7 fig, 2 tab, ref.

Descriptors: *Data acquisition, *Disposal si *Dredging wastes, *Monitoring, *Standar *Waste disposal, *Water quality, Bioassay, M uring instruments, Satellite technology, W quality control.

A preliminary set of guidelines are given for m toring aquatic, uncontaminated dredged mat disposal sites, and are intended to serve as a 'w ing' document that can be periodically improve experience dictates. Emphasis is placed on: (1) establishment of concise objectives and hyp eses; (2) the use of multidisciplinary approache developing monitoring programs; and (3) and provision of results that are relevant and usefi site managers. A 'tiered' step-wise proce which can be used when developing a monitc program is presented, along with a summary o basic tools and techniques for biological (suc bioassays with fish, shellfish, benthic infauna, submergent vegetation) and physical ana (such as satellites, bathymeters, fathometers, ment samplers, sediment-profiling cameras, wave meters). Ideally, monitoring of open dredged material disposal sites should be pro tive. Observations or measurements are tak determine if site conditions conform to de conditions. Monitoring can then focus on th tection of changes in specific conditions r than identifying any or all detectable chang monitoring program should be multi-tiered, each level having its own predetermined en mental threshold, hypothesis, sampling desig management options should the threshold b ceeded. APPLICATION OF A SIMPLE SHORT-T BIOASSAY FOR THE IDENTIFICATIO GENOTOXINS FROM HAZARDOUS WA
Environmental Health Research and Testing Research Triangle Park, NC.
S. S. Sandhu, and G. N. Acedo.
Available from the National Technical Inform Service, Springfield, VA 22161, as PB89-2 Price codes: AO3 in paper copy, AO1 in fiche. Report No. EPA/600/D-89/099. 198 2 fig, 4 tab.

Descriptors: *Aquatic plants, *Bioassay, *B cators, *Mutagenicity, *Pollutant identifi *Toxicity, *Water pollution effects, Arabi Economic aspects, Industrial wastes, Moni Testing procedures, Tradescantia, Zea.

The proper disposal of hazardous wastes cu generated and clean up of waste disposal the past are challenges facing regulatory a in the industrialized nations. The estima levels of toxicity is an essential step in pric industrial effluents and solid wastes for tr and disposal. A number of short-term bioas been developed to supplement informatic chemical analysis for evaluating the pote chemical complex mixtures to induce human health effects and environmental c nation. Among these bioassays, plant test provide simple, inexpensive, and rapid m evaluating toxic effects of industrial wast on multimedia exposure. Two such assays, cantia paludosa and Zea mays, have been monitoring the genotoxic effects of amb

municipal wastes, industrial effluents, solid wastes, water sediments, and pesticides. The Arabidopsis embryo assay was used to evaluate the mutagenicity of complex environmental mixtures including industrial effluents and sludges. The industrial waste samples were tested as either unextracted or as dichloromethane aqueous extracts. All methylene chloride-extracted samples were positive for mutagenicity; however, dose-related response was not observed for these extracts. For the aqueous extracts the NP3 and N-Hg recovery sludge samples showed dose-related mutagenic response although the mutagenicity values were much lower than that of NP2. The primary advantages of the plant bioassays are their simplicity, cost effectiveness, and utility in assessing simultaneous multimedia exposure. (Author's abstract)

1988, the Pacific Northwest Laboratory inlled a multiport groundwater sampling system in ll 399-1-2, drilled north of the 300 Area on the nford Site in southeastern Washington State. e purpose of installing the multiport system is to luate methods of determining the vertical distriion of contaminants and hydraulic heads in undwater. Well 399-1-20 is adjacent to a cluster our Resource Conservation and Recovery Act CRA) groundwater monitoring wells. This ximity makes it possible to compare sampling rvals and head measurements between the mulort sytem and the RCRA monitoring wells. lling and installation of the multiport system k 42 working days. Six sampling ports were alled in the upper unconfined aquifer at depths pproximately 120, 103, 86, 74, 56, and 44 feet. locations of the sampling ports were detered by the hydrogeology of the area and the ened intervals of adjacent groundwater moniig wells. The system was installed by backig sand around the sampling ports and isolating ports with bentonite seals. The method proved luate. For future installations, however, develent and evaluation of an alternative method is mmended. In the alternative method suggestthe multiport sytem would be placed inside a d and screened well, using packers to isolate ampling zones. (Author's abstract)

diation of polluted groundwater starts with curate evaluation of the degree and extent of the contamination. This evaluation requires a monitoring network and the network commonly increases in sophistication as the study progresses from preliminary evaluation to design of the remedial action. Surface geoelectrics have been combined with borehole information to define a plume of contaminated groundwater. The methodology allows for the uncertainty of the monitoring network to be quantified and for the design of the most effective expansion of a network. The methodology was applied to a plume at a low-level radioactive site in Rhode Island. Variograms for specific conductance were obtained from the direct borehole data, and were used with kriging techniques to estimate the areal distribution of specific conductance characterizing the extent and intensity of pollution. An accuracy analysis revealed the irregular pattern of well locations manifested by the reduced error estimates near monitoring wells. Mapping the interpreted electromagnetic data closely paralleled the direct data methodology. A variogram of the vertical dipole data was computed and used in the kriging process to map the electromagnetic data. Comparison shows a large degree of correlation between the location of high contamination levels. It is this correlation that can be employed to combine the two types of data (direct and geoelectric). The combination of data does reduce the estimation error and the reduction is measurable. ADAPTATION OF A LEAD-TESTING PROGRAM.

Hackensack Water Co., Harrington Park, NJ.
D. Hoven, B. Dietel, and V. Leiby.
Water Engineering and Management WENMD2, Vol. 137, No. 9, p 46-48, September 1990. 1 fig.

Descriptors: *Drinking water, *Lead, *Pollutant identification, *Schools, *Testing procedures, New Jersey, Public relations, Regulations, Water analysis, Water sampling.

In 1989, the Hackensack Water Company (HWC), Harrington Park, NJ, developed a lead-testing program for area schools. The program includes a one and one-half hour slide show and seminar that covers the following: (1) pertinent federal legislation and regulations, such as the Lead Contamination Control Act, the Lead Ban, and the Lead and Copper Rule; (2) the various sources of lead contamination, such as industries, lead-based paints and lead plumbing; (3) the sources of lead in drinking water, including source water contamination and contamination due to corrosion of fixtures, interior plumbing and service connections; (4) health effects of lead contamination, especially as it relates to children; (5) the HWC's sampling program; and (6) the types of remediation available to schools, such as removal of lead contaminated coolers, flushing, and replacing lead solder and pipes. Although the Environmental Protection Agency (EPA) guidance manual for lead in schools was used as the basis for the HWC program, a number of changes were made to decrease the burden on schools both from a cost and a manpower perspective. To avoid the necessity of developing a plumbing profile, which the EPA uses as a screening device to limit the number of samples collected and therefore the analysis costs, HWC decided to test all drinking water taps. No profiles are required unless a problem shows up. The HWC sampling program also maintains a consistent sampling protocol across all types of drinking water taps. The actual sampling scheme consists of two sampling rounds. The first step consists of first-draw samples collected from all sources of drinking water in the school, as well as from the service connection. Any sites yielding samples containing 20 parts per billion or more of lead are resampled in the second round. Round 2 sampling consists of a first draw for verification of the first-round sample result, a short flush of 30 seconds, and a longer flush of 3 minutes. Samples are then returned to the HWC laboratory where they are logged in and analyzed. In most cases, schools opt to flush the taps rather than investigate the causes. (Korn-PTT)

Applied and Environmental Microbiology AEMIDF, Vol. 56, No. 10, p 3170-3173, October 1990. 2 fig, 3 tab, 18 ref.

Descriptors: *Bacteriophage, *Bioassay, *Laboratory methods, *Monitoring, *Pollutant identification, Bacteria, Bioindicators, Fecal coliforms, Microbiological studies, Population density.

Bacteriophages of Escherichia coli are considered reliable indicators of the fecal pollution of natural waters. The direct double-agar-layer plaque assay for the detection and enumeration of specific bacteriophages of Bacteroides fragilis from contaminated-water samples was performed. Several factors that affect the methods, such as conditions of the bacterial culture, composition of the assay medium, addition of divalent cations, and decontamination techniques applied to the sample, were evaluated. The results obtained show that the direct assay technique is more efficient than the most-probable-number technique. The direct assay technique involves cells of the host bacteria being cultured with an atmosphere of 20% carbon dioxide and 80% nitrogen. Sample decontamination is performed by using membrane filtration (0.45 microm pore size) with membranes previously treated with 10 ml of 3% beef extract (pH 9.5). In the case of samples with a high degree of pollution, the medium should be supplemented with vancomycin and kanamycin. A higher recovery of bacteriophages was obtained from 17 of 24 samples with the direct assay. The two methods only showed similar results from samples with a low degree of pollution. (Brunone-PTT)

STABILITIES OF CARBOXYLIC ACIDS AND PHENOLS IN LOS ANGELES RAINWATERS DURING STORAGE.

California Univ., Los Angeles. Inst. of Geophysics and Planetary Physics.
K. Kawamura, and I. R. Kaplan.
Water Research WATRAG, Vol. 24, No. 11, p 1419-1423, November 1990. 4 fig, 18 ref.

Descriptors: *Carboxylic acids, *Chemistry of precipitation, *Phenols, *Pollutant identification, *Precipitation, *Sample preservation, *Water analysis, Acetic acid, Aromatic acids, Benzoic acid, Fatty acids, Formic acid, Hydrogen ion concentration, Los Angeles, Microbial degradation, Volatile aliphatic acids.

Organic compounds in rainfall may originate from biogenic or anthropogenic sources, or from photochemical reactions in the atmosphere. Concentration changes of acidic organic compounds (volatile aliphatic acids, fatty acids, aromatic acids and phenols) in rainwaters collected in Los Angeles, CA, were studied during storage experiments (up to 45 days). Carboxylic acids decreased with time in the order: benzoic acid < fatty acids < volatile acids. Although the observed losses have not been shown to result from microbial degradation, such a process is highly likely. Degradation of these acids, especially formic and acetic acids which are major components may result in a pH increase, during storage of rain. By contrast, toluic acids and phenols did not show a decrease in concentration after 2 weeks of storage indicating that these toxic compounds are resistant to microbial degradation in urban rainwater. Environmental Geology and Water Sciences

Group 5A—Identification Of Pollutants

EGWSEI, Vol. 16, No. 2, p 143-148, 1990. 4 fig, 1 tab, 7 ref.

Descriptors: *Analytical techniques, *Sludge analysis, *Suspended solids, *Trace metals, *Water treatment, Cadmium, Cobalt, Copper, Ion exchange, Iron, Japan, Leachates, Leaching, Lead, Manganese, Nickel, Organic matter, Oxides, River sediments, Silver, Sludge solids, Sulfides, Tin, Zinc.

In the analysis of natural water, it is of interest to determine quantities of trace metals in potable water sludges, since these trace metals, derived from yearly averages of suspended solids from the river, not only influence the environment, but will also help in investigating the mechanism of trace metals on solids suspended in river water. Fine sludges were collected from five filtration plants in Japan, and the partitioning of ten metals (Ag, Cd, Mn, Zn, Pb, Cu, Sn, Co, Ni, and Fe) in them was determined by selective leaching techniques. It was found that the available amounts, which show the total of each metal leached between 1 M CH3COONH4 and 30% H2O2, for Ag, Cd, and Mn, ranged from 51% to 98% for five sludges. The available amounts for Zn, Pb, Cu, and Sn were 47% to 92% for five sludges. The most important fraction for Co, Ni, and Fe, except the sludge from the Inagawa filtration plant which is markedly polluted by organic matter, was the crystalline particle. Therefore, the above metals, except Co, Ni, and Fe, are thought to be enriched on ion-exchangeable sites, organic matter, hydrous Fe/Mn oxides, and sulfides in fine sludges. (Author's abstract)

DETERMINATION OF PHOTOCHEMICALLY PRODUCED HYDROXYL RADICALS IN SEAWATER AND FRESHWATER.
Rosenstiel School of Marine and Atmospheric Science, Miami, FL. Div. of Marine and Atmospheric Chemistry.
X. Zhou, and K. Mopper.
Marine Chemistry MRCHBD, Vol. 30, No. 1/3, p 71-88, 1990. 4 fig, 3 tab, 37 ref.

Descriptors: *Chemical interactions, *Fate of pollutants, *Freshwater, *Photochemistry, *Pollutant identification, *Seawater, Chemical analysis, Degradation, Laboratory methods.

A variety of short-lived, reactive chemical species (free radicals and excited state species) are known to be photochemically produced in natural waters. Some of these transients may strongly affect chemical and biological processes, and they have been implicated in the degradation of organic pollutants and natural organic compounds in aqueous environments. Previous studies demonstrated that the highly reactive hydroxyl radical (OH) is photochemically formed in seawater. However, the quantitative importance of this key species in the sea has not been previously studied because of past analytical limitations. By using a highly sensitive probe based on alpha-hydrogen abstraction from methanol, production rates were measured of steady state concentrations of photochemically produced OH radicals in coastal and open ocean seawater and freshwaters. The validity of the method was tested by intercalibrating with an independent, OH-specific reaction, hydroxylation of benzoic acid, and also by competition kinetics experiments. OH production rates and steady state concentrations for freshwaters are in excellent agreement with those measured by previous investigators for similar waters. In contrast, for seawater, the values measured are 1-3 orders of magnitude higher than previously predicted by models, indicating that there is a major unknown photochemical OH source(s) in seawater. (Author's abstract)

HYDROCARBON POLLUTION IN PARTICLE-RICH WATERS (GULF OF FOS-SUR-MER): COMPARATIVE STUDY OF EXTRACTION PROCEDURES.
Centre d'Oceanologie de Marseille (France).
R. Siron, and G. Giusti.
Marine Chemistry MRCHBD, Vol. 30, No. 1/3, p 379-388, 1990. 1 fig, 2 tab, 30 ref. French Ministry of Science and Technology Grant No. DGRST 82-217.

Descriptors: *Chromatography, *Gulf of Fos-sur-mer, *Hydrocarbons, *Oil pollution, *Pollutant identification, *Water pollution sources, Alkanes, Chemical treatment, Coastal areas, Extraction, France, Lipids, Organic compounds, Particulate matter, Path of pollutants, Physical treatment.

The direct liquid-liquid extraction of hydrocarbons, without filtration of water supplies, can not be used for particle rich waters because of low yields and the selectivity towards particulate lipid classes. The ratios of hydrocarbons/total extractable matter and n-alkane/total hydrocarbons--as pollution indices--are altered in unfiltered water samples. The separation of dissolved and particulate phases and their specific extraction are indispensable for the complete recovery of the total hydrocarbons and alkanes from the water. Likewise, the n-alkane distribution and related Carbon Preference Index are influenced by the incomplete extraction of high molecular weight compounds in unfiltered samples. Conversely, the n-C17/pristane (Pr), n-C18/phytane (Phy) and Pr/Phy ratios are not significantly affected by direct extraction. However, these indices sometimes are strongly influenced by biological contributions. The Pr/Phy ratio generally seems to be convenient for characterization of the anthropogenic origin of hydrocarbons. (Author's abstract)

COMPARATIVE SURVEY OF IMPOSEX IN NORTHEAST PACIFIC NEOGASTROPODS (PROSOBRANCHIA) RELATED TO TRIBUTYLTIN CONTAMINATION, AND CHOICE OF A SUITABLE BIOINDICATOR.
Victoria Univ. (British Columbia). Dept. of Biology.
D. A. Bright, and D. V. Ellis.
Canadian Journal of Zoology CJZOAG, Vol. 68, No. 9, p 1915-1924, September 1990. 10 fig, 3 tab, 14 ref.

Descriptors: *Bioindicators, *Gastropods, *Organotin compounds, *Water pollution effects, Animal physiology, British Columbia, Comparison studies, Ecotoxicology, Field tests, Surveys.

Imposex, the manifestation of male morphological sex characteristics in females of functionally dioecious neogastropod taxa, is an abnormal response to tri-n-butyltin (TBT) contamination introduced to the marine environment in antifouling paints. Since the phenomenon has been thoroughly described only in Atlantic species, a comparative survey of field populations from British Columbia was undertaken, and field studies were carried out to assess the relative value as bioindicators of species in the genus Nucella from the Pacific coast. The majority of neogastropods studied to date have demonstrable signs of imposex, although this leads to sterilization of females in only a few species, depending on differences in the development in females of a pallial vas deferens. Within the Nucella species complex, N. lamellosa, N. canaliculata, and N. emarginata show promise as TBT bioindicators. Only the response of N. emarginata, however, was related to TBT bioaccumulation, based on measurements of a limited number of samples. This is attributed to the apparent irreversibility of imposex, the temporal variability of both environmental levels and tissue burdens of TBT, and considerably shorter life span of N. emarginata relative to that of N. lamellosa and N. canaliculata. The geographic distribution of imposex in Nucella spp. suggests that waterborne concentrations of TBT sufficiently high to induce imposex occur over large areas within British Columbia where exchange with oceanic water is limited. water surface sediments from eleven sites on
ver Derwent (Derbyshire, England) were
d monthly during the period of June 1987 to
988. Samples were extracted and separated
e polycyclic aromatic hydrocarbon (PAH)
was analyzed using high performance
chromatography with a fluorescence detec-
entity of the peaks was confirmed by co-
n and gas chromatography-mass spectrome-
anges in total levels of nine parent PAH
unds were compared with rainfall data ob-
for the study area. The time lag between
ncorporation into sediments and preceding
vents varied between a minimum of 4 and a
m of 30 days. All sites were affected by
PAH pollution. At certain sites and at times
y rainfall this contamination is overlaid by a
input of PAH to the sediment from point
sources. Road runoff was identified as a major diffuse source underlying atmospheric and point sources at particular sites. Small industrial areas had a greater influence on sediment PAH than the larger commercial or residential areas. Pyrene and fluoranthene were the dominant parent compounds, explained by their availability and relative solubility. (Author's abstract)

PAH AND ORGANIC CONTENT OF SEDIMENT PARTICLE SIZE FRACTIONS.
Derbyshire Coll. of Higher Education, Derby (England). Div. of Biology.
K. M. Evans, R. A. Gill, and P. W. J. Robotham.
Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 13-21, May 1990. 5 fig, 2 tab, 40 ref.

Descriptors: *Particle size, *Path of pollutants, *Polycyclic aromatic hydrocarbons, *Sediment contamination, Adsorption, Organic matter, Regression analysis.

The organic matter content of aquatic sediments has been shown to be very important in complexing hydrophobic toxic pollutants. The relationship of nine polycyclic aromatic hydrocarbons (PAH) with organic matter present in various Derwent River (Derby, England) sediment size fractions, from 63 microm to 1.0 to 2.0 mm, has been investigated. PAH and organic matter have bimodal distributions through the sediment size fractions which may be explained by the presence of two types of organic material in the sediment. Maxima in both factors are found in the two largest and the smallest size fractions. A positive linear relationship between PAH concentration and organic matter has been demonstrated and the slope of this relationship has been used to identify sites where PAH pollution is generally high. The relative proportion of each PAH compound in the sediment remains relatively constant regardless of temporal and spatial differences in total PAH concentration and organic matter content and certain PAH compounds may be grouped together depending on their association with organic matter. Differing PAH compound availabilities, competition for adsorption sites and the reactivity of PAH compounds may all result in the unchanging sediment PAH profile seen in each size fraction. The organic material present in the sediment may have a similar affinity for all PAH's in a particular group. (Author's abstract)

LEAD, ZINC, CADMIUM, AND FLUORIDE IN SMALL MAMMALS FROM CONTAMINATED GRASSLAND ESTABLISHED ON FLUOROSPAR TAILINGS.
Sunderland Polytechnic (England). School of Biology.
J. A. Cooke, S. M. Andrews, and M. S. Johnson.
Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 43-54, May 1990. 6 tab, 29 ref.

Descriptors: *Bioaccumulation, *Heavy metals, *Industrial wastes, *Mine wastes, *Path of pollutants, Cadmium, Fluorides, Lead, Metabolism, Waste disposal.

Waste materials produced by the fluorospar extraction industry contain high concentrations of a number of potentially toxic elements normally found only in trace amounts. These wastes are deposited in tailings lagoons or dams, which can be revegetated after dewatering. The total body concentrations of lead, cadmium, and fluoride were higher at such a site compared to an uncontaminated control site for three species of small mammals, Apodemus sylvaticus, Microtus agrestis, and Sorex araneus. Zinc was also higher in M. agrestis and S. araneus, but in A. sylvaticus it significantly decreased. There was evidence of homeostatic control of zinc in all three species even at the higher dietary intakes at the tailings dam. Accumulation in kidney, liver and bone (femur) showed the expected pattern with lead and fluoride highest in bone and cadmium in the kidney for both the control and the contaminated sites. The only exception was S. araneus at the contaminated site where cadmium was highest in the liver, not the kidney. The accumulation of lead, cadmium, and fluoride at the contaminated site was in the decreasing species order S. araneus > M. agrestis > A. sylvaticus in terms of total body concentrations or target organ concentration. This order probably reflects the decreasing dietary intake rates of the three species although physiological interspecific differences may be of significance. For example, S. araneus showed considerable capability to bioconcentrate cadmium to much higher body concentrations than present at the contaminated site. The lack of any consistent pattern of correlation for the tissue concentrations of lead, zinc, cadmium and fluoride is unexpected, but the small sample size may have prevented any significant correlations from being made. TRACE ELEMENT ACCUMULATION IN THE TISSUE OF FISH FROM LAKES WITH DIFFERENT PH VALUES.
Department of Energy, New York. Environmental Measurements Lab.
R. A. Stripp, M. Heit, D. C. Bogen, J. Bidanset, and L. Trombetta.
Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 75-87, May 1990. 7 tab, 37 ref.

Descriptors: *Acid lakes, *Acid rain effects, *Bioaccumulation, *Fish physiology, *Hydrogen ion concentration, *Path of pollutants, *Trace elements, Aluminum, Selenium, Spectrophotometry, Tissue analysis, Water chemistry.

Two species of fish, omnivorous Catostomus commersoni (white suckers) and carnivorous Perca flavescens (yellow perch) were collected from natural lakes with different pH ranges (circumneutral, pH 6.5 to 6.8; variable, pH 5.8 to 6.7; and acidic, pH 4.9 to 5.4). The lakes are located in the North Branch of the Big Moose River drainage system in the New York State Adirondack Park Preserve. Concentrations of potentially toxic elements (aluminum, cadmium, copper, lead, and selenium) were measured by electrothermal atomic absorption spectrophotometry in water, sediment, and fish (bone, gill, kidney, liver, and muscle) from each lake. The results showed that concentrations of lead and cadmium were significantly higher ($P < 0.05$) in some of the tissues of the fish collected from the acidic lake. Also, the yellow perch from the acidic lake had significantly higher ($P < 0.05$) selenium concentrations in their muscles and livers than fish from the other lakes. The concentrations of aluminum were elevated in the gill tissues of both fish species from the acidic lake relative to fish from the other lakes. (Author's abstract)

SPECIATION AND BEHAVIOR OF ARSENIC IN THE NILE DELTA LAKES.
Alexandria Univ. (Egypt). Dept. of Oceanography.
A. R. Abdel-Moati.
Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 117-132, May 1990. 4 fig, 3 tab, 31 ref.

Descriptors: *Arsenic, *Nile Delta, *Nonpoint pollution sources, *Path of pollutants, *Water pollution sources, Agricultural runoff, Coastal waters, Detergents, Fertilizers, Flushing, Herbicides, Mediterranean Sea, Phosphates, Retention time, Speciation, Wastewater pollution.

Dissolved and particulate arsenic species were measured in three Nile River coastal lakes in Egypt. Apart from input sources, arsenic levels lie within the range 1.2 to 18.2 microg/L (dissolved) and between 1.2 and 8.7 microg/g (particulate). Arsenic (V) is the predominant dissolved arsenic species constituting between 85% and 95% of total dissolved arsenic (TDA). Opposite to local sewage discharge points, arsenic (III) appeared, constituting between 14% and 33% of TDA at low and high water discharge periods, respectively. Dimethylarsenic is the dominant organic arsenic form, reaching 22% of TDA while the maximum concentration of monomethylarsenic (1.0 microg/L) constituted about 8% of TDA. Particulate arsenic is mostly partitioned among reducible and detrital phases while the organic phase appeared

dominant in eutrophic areas (> 30% of particulate arsenic). About 413 tons/year arsenic entered the northern delta lakes via agricultural drains and wastewater discharge. Phosphate fertilizers, detergents, herbicides, and loamy Nile deposits are the main arsenic sources to the drainage system. Fifty-two percent of the total arsenic deposited in the Nile delta lakes is transported to the Mediterranean coastal seawater through the lakes outlets. This amount is potentially hazardous to the coastal environment. (Author's abstract)

SOLUTE TRANSPORT THROUGH SATURATED SOILS: A STUDY OF THE PHYSICAL NON-EQUILIBRIUM MODEL.
Claremont Graduate School, CA. Dept. of Mathematics.
G. Mahinthakumar, and S. Vigneswaran.
Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 161-180, May 1990. 10 fig, 3 tab, 17 ref, 2 append.

Descriptors: *Fate of pollutants, *Groundwater pollution, *Model studies, *Path of pollutants, *Saturated soils, *Soil contamination, *Solute transport, Adsorption, Equilibrium, Mass transfer, Soil physical properties, Solutes.

A two-region physical non-equilibrium transport model incorporating mobile and immobile regions (Van Genuchten and Wieringa model) was used to predict the movement of solutes through saturated soils. Freundlich's nonlinear isotherms were coupled with this transport model to account for the adsorption phenomena. A CSMP III (Continuous System Modeling Program) program was used to solve this problem numerically. The model was tested for 3 sets of experimental data having different soil and solute properties. The experimental curves were fitted by adjusting the 3 parameters, mass transfer coefficients, distribution factor for sorption sites in the mobile region, and the fraction of mobile water content. The model predicted well only for fairly conservative solutes. To predict the movement of highly reactive solutes, such as cadmium, the model needs further modification. Effects of dispersion coefficient, mass transfer coefficients, distribution factor for sorption sites in the mobile region, and the fraction of mobile water content on the breakthrough curves were studied for highly reactive solutes (a term used for solutes with high adsorption coefficient and high mass transfer coefficient), although these effects were significant for mild solutes. Solute concentration profiles for a semi-infinite column (as in the field situation) were predicted for 3 different cases and the penetration depths were compared with those obtained from Green and Ampt profiles. A Green and Ampt profile was a good approximation for finding the penetration depths in environmental impact assessment studies for mildly reactive solutes exhibiting fairly sharp solute fronts. UPTAKE OF CADMIUM AND NICKEL IN BANANA PRAWN (PENAEUS MERGUIENSIS DE MAN).
Balai Penelitian Veteriner, Bogor (Indonesia). Toxicology Section.
D. Darmono.
Bulletin of Environmental Contamination and Toxicology BECTA6, Vol. 45, No. 3, p 320-328, September 1990. 9 fig, 16 ref.

Descriptors: *Bioaccumulation, *Bioindicators, *Cadmium, *Marine animals, *Nickel, *Path of pollutants, *Shrimp, *Water pollution effects, Animal tissues, Dose-response relationships, Experimental data, Heavy metals.

The patterns of nickel and cadmium accumulation were measured in juvenile banana prawns (Penaeus merguiensis de Man). Prawns were exposed to the test metals (0-0.5 mg/L Cd or 0-2.0 mg/L Ni) for up to 30 d with replacement of the metal solutions every 3 d. At all experimental levels of exposure, Cd was most concentrated by the hepatopancreas and least concentrated by muscle over the 30 d period. Ni was accumulated to the greatest extent by the hepatopancreas followed by the gills and then the muscle. For both Cd and Ni, the rates of uptake were linearly related to the metal concentration in the seawater over the concentration ranges studied. For Ni in all tissues, the relationship approximated one of direct proportionality, implying little metabolic control over uptake at the levels tested. A similar trend was observed for Cd in muscle tissue. The accumulation of Cd in all tissues was greater than for Ni, despite lower Cd test concentrations used. This suggests that the cell membranes are more permeable to Cd than to Ni which may account for the greater toxicity of Cd to these organisms. The limited ability of prawns to control uptake of either metal against changes in external concentrations suggests that they may have potential as bioindicators of pollution by Ni and Cd. BARIUM BIOACCUMULATION IN CLAMS COLLECTED FROM DIFFERENT SALINITY REGIMES ALONG THE SAUDI COAST OF THE ARABIAN GULF.
University of Petroleum and Minerals, Dhahran (Saudi Arabia). Water Resources and Environment Div.
M. Sadiq, T. H. Zaidi, and H. Al-Mohana.
Bulletin of Environmental Contamination and Toxicology BECTA6, Vol. 45, No. 3, p 329-335, September 1990. 1 fig, 2 tab, 7 ref.

Descriptors: *Barium, *Bioaccumulation, *Mollusks, *Path of pollutants, *Persian Gulf, *Salinity, *Saudi Arabia, Clams, Marine pollution, Oil industry, Sediment contamination.

Barium bioaccumulation by clams (Maritrix maritrix) as a function of sediment concentration and seawater salinity was investigated along the Saudi coast of the Arabian Gulf. Samples of clams, seawater and sediment were obtained quarterly from each of 12 stations between March 1985 and April 1986. The maximum concentrations of Ba were found in sediments from Stations 8 and 12, both of which were probably affected by the drilling muds during the development of Beri and Manifa oil fields, respectively. The maximum Ba concentrations in clams were found in those from Station 12. No significant correlation between Ba concentrations in sediments and mean clam concentrations were found when all the data were considered. Removing the data for Stations 1 and 12 resulted in a significant linear correlation. No effect of salinity on Ba bioaccumulation by clams was found. (MacKeen-PTT)

FATE OF PARATHION IN GROUND WATER IN COMMERCIAL CRANBERRY CULTURE IN THE NEW JERSEY PINELANDS.
Cook Coll., New Brunswick, NJ. Dept. of Environmental Science.
G. Winnett, P. Marucci, S. Reduker, and C. G. Uchrin.
Bulletin of Environmental Contamination and Toxicology BECTA6, Vol. 45, No. 3, p 382-388, September 1990. 2 fig, 2 tab, 14 ref.

Descriptors: *Agricultural chemicals, *Agriculture, *Cranberries, *Groundwater pollution, *New Jersey, *Parathion, *Path of pollutants, *Pesticides, Aquifer testing, Bogs, Cohansey aquifer, Risk assessment, Soil contamination, Surface water, Surface-groundwater relations.

The possible contamination of groundwater resulting from the recent use of parathion (O,O-diethyl O-4 nitrophenyl phosphorothioate) and its horizontal and vertical movement in the bog soil of the Cohansey aquifer, New Jersey, were examined. Parathion was applied by spray boom at 1 pound per acre three times per growing season. Surface waters and groundwaters were sampled weekly or biweekly for one year for the parathion-treated bog and a control bog. In general, parathion which was the New Jersey Agricultural Station's recommendation to the cranberry growers of New Jersey, showed no discernible vertical movemen in the experimental bog from the surface water t the groundwater. There appears to be no correla tion between the residues found in the surfac water and soil with those few found in the ground water. Where residues of parathion are found i the soil, concentrations are highest in the uppe stratum. It thus appears that there is little danger c parathion pollution from applications made i normal cranberry culture at these sites. (MacKeer PTT)

The presence of residual organochlorine inse cides (OCIs) such as HCH and DDT was stud in different sources of drinking water in around Bhopal, India. A total of sixty sam from different wells, handpumps and ponds w analyzed for OCIs by gas-liquid chromatogra and thin layer chromatography. HCH and D were detected in all samples tested. Water sam from wells had mean residual contents of 4.7 p HCH and 5.8 ppm DDT. Samples obtained fi handpumps had on average 6.1 ppm residual H and 14.5 ppm residual DDT. Mean residual H and DDT contents of 9.9 ppm and 16.1 ppm v detected in pond water samples. The alpha iso of HCH was most prevalent in all three w sources (52-53%), followed by beta (33-37%) gamma (10-14%). pp'-DDT and its metabo such as pp'-DDE and pp'-DDD were also four almost all the water samples, possibly indica metabolic conversion and dehydrochlorina Due to the carcinogenic and esterogenic pote of OCIs and their metabolites, regular monito of the drinking water on a national basis is rec mended. RESIDUES OF ORGANOCHLORINE INSE CIDES IN FISH FROM MAHALA WATER R ERVOIR, JAIPUR, INDIA.
Rajasthan Univ., Jaipur (India). Dept. of Zoo P. P. Bakre, V. Misra, and P. Bhatnagar.
Bulletin of Environmental Contamination Toxicology BECTA6, Vol. 45, No. 3, p 39 September 1990. 1 tab, 15 ref.

Descriptors: *Chlorinated hydrocarbons, *India, *Insecticides, *Path of pollutants, cide residues, Aldrin, Benzene hexachloride, Fish diets, Halogenated pesticides, Jaipur, Reservoir, Metabolites.

The levels of organochlorine insecticide (OC dues were measured in different fish species the Mahala Reservoir, a freshwater lake situa km from Jaipur, India. Pesticides used in the ment area (220 sq miles) are carried in agric

runoff from land to water where they are adsorbed on bottom sediments and may move to other components of the aquatic system. Sixty-four fish of four species were collected between November 1986 and September 1987 (12 Puntius sarana, 24 Channa punctatus, 12 Wallago attu, and 16 Labeo bata) and tested for residues of alpha-, beta-, and gamma-HCH, aldrin, p,p'-DDT, DDE, and DDD. The highest OC residue quantities were detected in L. bata, a bottom feeder, the lowest in C. punctatus, which has a diversified diet with a large plankton share. A comparison of OC residue levels in various tissues indicated that the lowest levels were found in muscle, probably due to the low fat content and lack of active metabolic role for OC in muscle tissue. mary effluents from the Deer Island and Nut and wastewater treatment plants discharged to ssachusetts Bay and proposed secondary efents were tested for toxicity. The average conntrations of dissolved oxygen in unchlorinated d chlorinated samples were 2.8 and 6.5 mg/L, pectively. Total residual chlorine (TRC) conntrations in secondary effluents were similar for h samples and ranged between 1.0 and 1.12 mg/ The results of the 7 day toxicity renewal test cated that the survival of sheepshead minnows unchlorinated effluent samples collected from n plants was significantly reduced compared n survival in chlorinated effluents. The results he 96 h static acute toxicity tests indicated that rival of mysids in the chlorinated effluents was ced when compared with survival in unchlored effluents; however, mysid response to chlo- was not substantial. Sea urchin sperm cell city tests showed that toxicity of each effluent ed throughout the program. Generally, the rinated primary effluents were more toxic than unchlorinated, and Nut Island effluents desed sperm viability more than Deer Island ents. The unchlorinated and chlorinated secary effluents were minimally toxic to sea in. Overall, the results of the study indicated the wastewaters currently discharged to on Harbor are toxic, however the source of oxicity is unknown. The chlorination treatcurrently used at both treatment facilities ases the TRC concentration in the primary ents and exaggerates the toxicity of the ewaters. Biological monitoring conducted in uture on effluent discharged from the new ndary treatment plant should include assess of the short-term and long-term biological s of the discharged wastewaters. For short- biomonitoring, the sea urchin fertilization test ommended because it includes the evaluation production potential, is conducted in minutes, s sensitive and simple to conduct. (MacKeen-

UENCE OF PHYSIOLOGICAL CONDI- ON CADMIUM TRANSPORT FROM HAEMOLYMPH TO HEPATOPANCREAS IN CARCINUS MAENAS.
Odense Univ. (Denmark). Biological Inst.
P. Bjerregaard.
Marine Biology MBIOAJ, Vol. 106, No. 2, p 199-209, 1990. 10 fig, 3 tab, 43 ref.

Descriptors: *Bioaccumulation, *Cadmium, *Crabs, *Dose-response relationships, *Marine animals, *Path of pollutants, Absorption, Crustacea, Heavy metals, Hemolymph, Hepatopancreas, Ion transport, Proteins.

Accumulation and binding of cadmium in the tissues of the shore crab Carcinus maenas (L.) were investigated in a series of laboratory experiments. Cadmium was removed from the hemolymph with a half-life of approximately 10 h, and half of the cadmium removed from the hemolymph was taken up in the hepatopancreas. The efficiency with which individual crabs transported cadmium from the hemolymph to the hepatopancreas was strongly related to physiological parameters, such as concentrations of calcium and magnesium in the hepatopancreas, hemolymph volume and hemolymph protein concentration. The transport of cadmium from the hemolymph to the hepatopancreas was saturated in crabs exposed to more than 2-4 mg/L of cadmium in the seawater. In the hepatopancreas of unexposed crabs, cadmium was bound mainly in the insoluble tissue fraction (40%) and in the protein fraction with a molecular weight of approximately 6,000 D (50%). Exposure to 0.25-1.5 mg/L cadmium for 2 w led to dose-dependent increases in the amounts of cadmium bound in the high-molecular weight protein fraction and in the insoluble tissue fraction. Cadmium may be transported from hemolymph either as free ions (actively or passively), transported with hemocyanin in a pinocytotic process or transported with amoebocytes. (Author's abstract)

APPLICATION OF TWO-SITE/TWO-REGION MODELS FOR STUDYING SIMULTANEOUS NONEQUILIBRIUM TRANSPORT AND DEGRADATION OF PESTICIDES.
Florida Univ., Gainesville. Dept. of Soil Science.
A. P. Gamerdinger, R. J. Wagenet, and M. T. van Genuchten.
Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 957-963, July/August 1990. 5 fig, 4 tab, 21 ref.

Descriptors: *Degradation, *Fate of pollutants, *Mathematical models, *Path of pollutants, *Pesticides, *Sorption, Atrazine, Computer programs, Equilibrium, Isotherms, Organic compounds, Pore water, Soil columns, Soil contamination, Solute transport.

Quantitative laboratory study of pesticide sorption and degradation during transport can provide insight into the basic processes affecting pesticide fate in field soils. Accordingly, the application of analytical solutions of two-site/two-region transport models useful in studying simultaneous pesticide sorption and degradation, were demonstrated. Soil column displacement experiments involving tritiated water, Cl and atrazine (2-chloro-4-ethylamino-6-isopropylamino-s-triazine) were conducted during steady-state water flow at two pore water velocities and two pesticide concentrations. The soil used was a Valois silty loam (coarse-loamy, mixed, mesic Typic Dystrichrept). Effluent data from these experiments were used to demonstrate the application of these analytical solutions, as well as a parameter estimation computer program based on these solutions. The ability to use laboratory-derived estimates of equilibrium sorption parameters to describe sorption under flowing conditions was evaluated at each flow velocity. Significant correlation between soil sorption partitioning and degradation prevents the simultaneous determination of both processes using these solutions. However, estimates of degradation obtained from mass balances of the column data were useful in identifying the equilibrium sorption parameters. Data collected elsewhere for 2,4,5-T (2,4,5-trichlorophenoxyacetic acid) herbicide transport were used as an additional example of the application of the model with degradation. These techniques are applicable to other organic chemical contaminants. (Author's abstract)

ORGANIC SELENIUM DISTRIBUTION IN SELECTED CALIFORNIA SOILS.
Oregon Graduate Inst. of Science and Technology, Beaverton. Dept. of Environmental Science and Engineering.
M. M. Abrams, R. G. Burau, and R. J. Zasoski.
Soil Science Society of America Journal SSSJD4, Vol. 54, No. 4, p 979-982, July/August 1990. 3 fig, 2 tab, 21 ref.

Descriptors: *Agricultural runoff, *California, *Kesterson Reservoir, *Organic compounds, *Path of pollutants, *Selenium, *Soil chemistry, *Subsurface drainage, *Water pollution sources, Fulvic acids, Gas chromatography, Humic acids, Mass spectrometry, Organic matter, Soil types, Topography.

The distribution of organic Se was determined in seven soils from central California. Six of these soils (one Typic Pelloxerert, three Typic Torriorthents, one Vertic Torriorthent, and one Entic Chromoxerert) were in a toposequence from an area thought to be relatively high (>1000 microg total Se/kg) in native Se, because of the high Se levels in the subsurface agricultural drainage water pumped into the Kesterson Reservoir (California). The seventh soil, Yolo (a Typic Xerorthent), thought to be low in native Se, was included for comparison. Three of the soils in the toposequence had total Se levels less than 1000 microg/kg; the basin soil (Tachi; Typic Pelloxerert) had less than the Yolo soil. A solution of 0.1 M NaOH/0.1 M alkaline pyrophosphate extracted an average of 12% of the total Se, ranging from 5 to 32%. Organic Se accounted for 50% or more of the NaOH/alkaline pyrophosphate extractable Se in all but the poorly drained Ciervo clay (Typic Torriorthent), which had about 40% in an organic form. Extracted organic Se compounds were fractionated into humates and hydrophobic fulvates. Selenium associated with hydrophobic fulvates was high in the soils of intermediate toposequence elevation. Selenomethionine was identified by gas chromatography/mass spectrometry in the hydrophilic fulvate fraction of the Yolo soil and in three soils from the toposequence. The high percentage of extractable Se associated with organic matter in these soils represents a pool of Se potentially available to plants. (Author's abstract)

TRITIUM, OXYGEN-18, AND DEUTERIUM DIFFUSION AT THE CONFEDERATION ROAD LANDFILL SITE, SARNIA, ONTARIO, CANADA.
University of Western Ontario, London. Faculty of Engineering Science.
E. K. Yanful, and R. M. QR. M. Quigley.
Canadian Geotechnical Journal CGJOAH, Vol. 27, No. 3, p 271-275, June 1990. 4 fig, 1 tab, 19 ref.

Descriptors: *Deuterium, *Diffusion, *Landfills, *Leachates, *Ontario, *Oxygen isotopes, *Path of pollutants, *Tracers, *Tritium, Biodegradation, Chemical interactions, Chemical reactions, Chlorides, Clay liners, Clays, Diffusion coefficient, Ficks Law, Infiltration, Isotopes, Sodium.

The Confederation Road Landfill is a closed municipal landfill situated about 6.4 km east-southeast of Sarnia, Ontario. The isotopes tritium, oxygen-18, and deuterium, which appear to have been concentrated in the leachate at the site, are shown to have migrated into the underlying natural clay barrier by molecular diffusion. The theoretical best-fits to the observed concentration profiles, using the error function solution to the transient diffusion equation (analogous to Fick's second law), give diffusion coefficients (in square centimeters per second) of 0.000013 for both oxygen-18 and deuterium, and 0.0000085 for tritium. Field concentration profiles for Cl(-) and Na(+) yielded diffusion coefficients of 0.0000064 for chloride and 0.0000033 for sodium (also square cm/s). Tritium and chloride appear to have migrated a similar

distance of approximately 2.0 m from the clay-waste interface, compared with only 1.2 m for sodium, which has probably been retarded by adsorption onto clay exchange sites. Oxygen-18 and deuterium appear to have migrated the furthest at approximately 2.3 m. The tritium profile indicates that post-1953 rainwater entered the landfill site, probably mostly in 1967 when the landfill trench was excavated. High delta O18 and delta deuterium values, especially near the clay-waste interface, suggest mixing of 1967 rainwater with an isotopically enriched water, probably produced in the landfill either directly from enriched organic wastes such as leaves or by biodegradation processes. The subsurface transport of dissolved organic carbon (DOC) through a proposed waste burial site during rain events was investigated in order to assess the role of colloid-mediated contaminant mobility. A sub-watershed (0.45 ha) located on a forested hillslope in eastern Tennessee was instrumented with an isolated soil pedon for one-dimensional transport studies, and a subsurface weir monitoring system for three-dimensional transport studies. The source of DOC in the soils resulted from dissolution of organic matter in the surface horizon during and between rain events, as well as from a highly reactive B horizon which stored significant quantities of DOC in small pores. During large storms, the concentration of DOC was similar on ascending and descending limbs of the subsurface hydrograph, with a maximum concentration occurring at peak flow. During small storms chemical interactions with soil solution SO4(--) caused DOC concentrations to be greater on the ascending limb of the hydrograph, with maximum DOC concentrations occurring before peak flow. Because subsurface lateral flow through preferential paths predominated in the Bt2 and Bt3 horizons of the soil during storm events, the total cumulative flux of DOC downslope was generally much greater through the lower soil horizons. A significant component of mobile DOC consisted of hydrophobic organic solutes, even though this material was selectively adsorbed with soil depth relative to hydrophilic organic solutes. The significant mobility of hydrophilic DOC may enhance the environmental transport of contaminants. (Author's abstract)

PERSISTENCE OF ALDICARB RESIDUES IN THE SANDSTONE AQUIFER OF PRINCE EDWARD ISLAND, CANADA.
Canada Centre for Mineral and Energy Technology, Elliot Lake (Ontario). Elliot Lake Lab.
R. E. Jackson, J. P. Mutch, and M. W. Priddle.
Journal of Contaminant Hydrology JCOHE6, Vol. 6, No. 1, p 21-35, July 1990. 10 fig, 1 tab, 16 ref.

Descriptors: *Agricultural chemicals, *Aldicarb, *Carbamate pesticides, *Groundwater, *Groundwater pollution, *Path of pollutants, *Pesticide residues, *Pesticides, *Prince Edward Island, Aquifer characteristics, Glacial sediments, Groundwater movement, Groundwater quality, Half-life, Hydrogen ion concentration, Sandstones, Sorption.

Aldicarb residues were found in the shallow groundwaters of the fractured sandstone aquifer of Prince Edward Island more than two years after the last application of the pesticide. Concentrations of aldicarb measured were relatively constant with time. It is deduced that the detoxifying abiotic transformation (hydrolysis) of aldicarb is inhibited by the low pH and temperature of the soil and groundwater, the former being partly due to the pH-buffering effects of ammonium fertilizer oxidation. Aldicarb residues remain constant and relatively high because their storage within the sandstone matrix and subsequent diffusion back into the fractures of this dual porosity system. Attempts to simulate the observed persistence of aldicarb in this hydrogeologic environment using a one-dimensional, solute transport simulation code were unsuccessful, probably because of the three-dimensional nature of the matrix diffusion process. The simulation suggested that the overall half-life for aldicarb in the till-sandstone system approaches 150 days. These results indicate that aldicarb is not readily degraded in the hydrologic system, and that some insitu storage mechanism is retaining undegraded aldicarb species and slowly releasing them over time. Mechanisms possibly playing a role include sorption of aldicarb and its slow release, downslope migration of aldicarb within the flow system, inhibition of degradation, slow infiltration through the unsaturated till overlying the sandstone, and matrix diffusion within the sandstone and slow release. MODELING THE MASS-TRANSFER RATE OF RADIOACTIVE COBALT FROM A SYNTHETIC GROUNDWATER TO VOLCANIC TUFF MEDIA.
Howard Univ., Washington, DC. Dept. of Chemical Engineering.
M. G. Rao, H. R. Fuentes, W. L. Polzer, and E. H. Essington.
Journal of Contaminant Hydrology JCOHE6, Vol. 6, No. 1, p 69-84, July 1990. 6 fig, 3 tab, 14 ref. U. S. Nuclear Regulatory Commission Grant No. NRC/FIN/A7150.

Descriptors: *Cobalt radioisotopes, *Groundwater pollution, *Mass transfer, *Model studies, *Path of pollutants, *Radioactive waste disposal, *Tuff, Adsorption kinetics, Diffusion, Radioactive wastes, Radiochemical analysis, Radioisotopes.

A factor affecting the retention of ions by solids is diffusion from the bulk of a solution to the inner portion of solid particles and the rate-determining step is either film or particle diffusion or both. The application of a shrinking-core model controlled by macroporous diffusion has been validated for the adsorption kinetics of radioactive Co from a 0.01N CaCl2 solution to Bandelier Tuff. This tuff has served as a natural barrier in the disposal of low-level radioactive waste at Los Alamos National Laboratory. The model is validated for duplicate experiments and also in binary and ternary combinations with Sr and Cs. The sorbates were initially in solution at 20 mg/L and were contacted with the tuff in bottles agitated in the batch mode at 25C. Co adsorbs irreversibly to the particle and is not available for transfer to the nonreacted portion or inner core of the particle. Unlike traditional models of rate control such as chemical reaction, film and particle diffusion, the shrinking-core model predicts increased mass-transfer rates with an increase in the concentration of Co in the liquid phase. The results have direct implications in the understanding and modeling of the fate and transport of radioactive Co in volcanic tuffs. Volcanic tuff is also being considered as a medium for the location of a high level nuclear waste repository in the state of Nevada. (Tappert-PTT)

ADSORPTIVE SOLUTE TRANSPORT IN FRACTURED ROCK: ANALYTICAL SOLUTIONS FOR DELTA-TYPE SOURCE CONDITIONS.
Kyoto Univ., Osaka (Japan). Research Reactor Inst.
Y. Fujikawa, and M. Fukui.
Journal of Contaminant Hydrology JCOHE6, Vol. 6, No. 1, p 85-102, July 1990. 6 fig, 3 tab, 15 ref, 2 append.

Descriptors: *Adsorption kinetics, *Fracture permeability, *Mathematical models, *Path of pollutants, *Radioactive waste disposal, *Solute transport, Analytical models, Breakthrough curves, Geologic fractures, Tracers.

Solutions for adsorptive solute transport equations in a single fracture-rock system were derived under two different delta-type source conditions. One was the delta-type, flux injection condition. The correspondent solution can be used for the analysis of experimental column breakthrough curves obtained by injecting the tracer into the rock fracture. The other was the delta-type, resident fluid injection condition. The solution can be used for the crude estimation of pollutant migration from the underground radioactive waste repository. In formalizing the resident fluid injection an initial distribution of solute between solution and solid phase was assumed in order to satisfy the mass balance between injected and detected solute. Each of the two solutions was also expressed in two ways reflecting the flux and the resident fluid detection. Solutions expressed in terms of the fluid detection correspond to the effluent concentration measured experimentally by a fraction collector system. On the other hand, solutions expressed in terms of the resident fluid detection describe spatial distribution of the solute in the fluid. Since considerably long tailings of breakthrough curves are often observed in column tracer experiments using fractured rocks, effects of some parameter values on the tailing were also investigated. It was shown that the adsorption of solute to rock matrix caused longer tailing. It was also shown that the resident fluid injection caused longer tailing in breakthrough curves than the flux injection condition. (Author's abstract)

ENVIRONMENTAL CHEMISTRY AND B LOGICAL EFFECTS OF CADMIUM CO POUNDS.
International Association of Environmental A lytical Chemistry, Therwil (Switzerland).
E. Merian.
Toxicological and Environmental Chemi TXECBP, Vol. 26, No. 1/4, p 27-44, 1990. 1 fig tab, 58 ref.

Descriptors: *Cadmium, *Heavy metals, *Path pollutants, *Reviews, *Toxicology, *Water p tion effects, Air pollution effects, Analytical m ods, Bioaccumulation, Pathology, Population posure.

The toxic metal cadmium and its compounds distributed ubiquitously in the earth's crust. Ca um uptake occurs by ingestion and inhala Smoking also plays a role, since tobacco con cadmium. Cadmium commonly occurs as v soluble bivalent compounds and can be anal by atomic absorption, isotope dilution mass trometry, and neutron activation analytical m ods. Most of the world production of cadmi used in the electroplating of iron and steel manufacture of nickel-cadmium batteries; addi al uses include pigments, soaps, alloys for cells, and neutron absorbers in nuclear p plants. In the environment, cadmium is taken plants much more readily than other heavy m High cadmium concentrations in compost, se sludge, and upper soil layers may reduce the

ers of microorganisms necessary for rapid decomposition of organic material, and nitrogen fixation ay also be reduced. Plants and fish bioaccumulate admium. Measurements of particulate airborne admium intake via the respiratory tract indicate tention rates of 10 to 40%, with broad variations nong mammals in lung deposition and biological lf-life. Detoxification is performed by cytosolic oteins such as metallothioneins. Symptoms of dmium uptake in plants include chloroses and croses with characteristic color changes. Inease of salinity and/or calcium content and dimition of temperature in aquatic environments deease cadmium toxicity. Terrestrial animals are commonly exposed to doses that produce toxic ects. In humans, ingestion of cadmium levels gher than 15 ml/L causes vomiting. Inhalation of dmium at levels greater than 1 mg/cu meter can oduce shortness of breath, weakness, and fever. vels of 5 mg/cu meter may be lethal after eight urs exposure. There is no clear evidence for tagenesis. Data from animal experiments sugt cadmium may have the potential to be a cinogen, although epidemiological data is conng and requires further study. Studies on reprotive effects and teratogenicity have mainly n conducted on rodents, and the evidence is not r. Relatively high single cadmium doses may treated with chelators. Threshold values are stantly being revised as more data becomes ilable. (Tappert-PTT)

SEPTIC TANK AND AGRICULTURAL NON-POINT SOURCE POLLUTION WITHIN A RURAL WATERSHED.
Texas Christian Univ., Fort Worth. Environmental Sciences Program.
S. Hayes, L. Newland, K. Morgan, and K. Dean.
Toxicological and Environmental Chemistry TXECBP, Vol. 26, No. 1/4, p 137-155, 1990. 2 fig, 7 tab, 65 ref.

Descriptors: *Agricultural runoff, *Agricultural watersheds, *Ammonia, *Coliforms, *Nonpoint pollution sources, *Rural areas, *Septic tanks, *Water pollution effects, Rainfall, Soil conservation, Water pollution sources.

An increased interest in water quality improvement has resulted in the creation of special programs to promote the adoption of soil conservation practices. Non-point source (NPS) pollution derived from sediment infusion is specifically addressed in the latest version of the Clean Water Act. The Lake Weatherford reservoir in Parker County, Texas is the primary municipal water supply for the City of Weatherford, Texas. The principal method of wastewater disposal is the on-site system or septic tanks for the small residential areas surrounding the reservoir. Sources of NPS pollution of interest in this watershed include agricultural operations as well as the residential areas. These sites were identified with the aid of aerial photography and field investigation. Suspected NPS problems were substantiated through a sampling program involving chemical and biological testing of the reservoir. Results indicate that there is significant NPS pollution contamination of Lake Weatherford from agricultural sources and seepage from on-site wastewater disposal systems. Excessive fecal coliform and fecal streptococcus counts were generally associated with rainfall events, and several samples showed values greater than 100,000 bacteria per 100 ml. The fecal coliform/fecal streptococcus ratios indicated contamination from human sources, animal sources, and a combination of both. Nutrient concentrations fluctuated from quite low to high with ammonia as the most consistent problem. High ammonia values were also associated with rainfall events. (Author's abstract)

TRACE METALS IN THE WESTERN MEDITERRANEAN SEA.
Istituto di Biofisica, Pisa (Italy).
A. Seritti, E. Morelli, L. Nannicini, and G. Scarano.
Toxicological and Environmental Chemistry TXECBP, Vol. 26, No. 2/3, p 87-93, 1990.

Descriptors: *Cadmium, *Copper, *Lead, *Mediterranean Sea, *Path of pollutants, *Trace metals, *Water pollution sources, Data collections, Distribution patterns, Particulate matter, Seawater, Water sampling.

Data on Cd, Pb, and Cu concentrations in seawater were determined from samples collected during five years of field studies in the western Mediterranean Sea. The data present a space and time integrated status of the levels of these metals. Sampling locations included areas near known sources of industrial discharges. Surface total metal concentrations present rather homogeneous distributions over the different areas considered, including the Tyrrhenian Sea (off Italy in the eastern part of the study area). The metal concentrations in three areas affected by natural and industrial wastes are not significantly different from data reported from other areas of the Mediterranean. Averages and ranges of metal concentrations found in particulate matter in the Tyrrhenian Sea seem to be rather low, although the ranges are larger than those in the dissolved fraction, particularly for Pb and Cu. The data indicate the high affinity of metals for particulate matter. The vertical distribution of dissolved Cd, Pb, and Cu in the Alboran Sea (in the western part of the study area, between Spain and North Africa) seems to be rather homogeneous, both vertically and along a series of stations between the Strait of Gibraltar and the island of Alboran. A numerical technique has been developed that appears to have potential in studies of nonlinear reactive transport problems, and it is applied to a case study where the implications of reactive transport processes are profound. The case study relates to the Fuhrberger Feld aquifer in northern Germany, which provides the bulk of the water supply for the half-million people living in the city of Hannover. Part of the aquifer receives a strong influx of nitrate from agricultural activities. The nitrate in the aquifer is microbially transformed into sulfate, the transformation depending on the availability of reduced sulfur compounds present in the sediment. The individual transformations occur within distinct reaction zones in the aquifer. The relevant dynamic processes can be formulated as a nonlinear transport problem involving multiple interacting species in dissolved or solid form. The system is simulated using a finite element-based technique that generates a symmetric coefficient matrix for the transport equation, while providing second-order accuracy in time. The form of the matrix allows the use of a highly efficient and robust symmetric conjugate gradient solver. The technique provides an ample spatial resolution capacity at reasonable cost, and handles grids with irregular geometry in two or three dimensions. The convenience and versatility of conventional finite elements is retained. A vertical-section simulation identifies different reaction zones in the aquifer and gives insight into the effect of the controlling parameters. The simulation study is a first step in the development of a prognosis for the fate of the groundwater resource. (Author's abstract)

The bromide plume at the Borden site (Ontario, Canada) has been extensively investigated by researchers from Stanford University and the University of Waterloo. Seven solutes, including Br and Cl, were injected into the Borden aquifer in 1982. Chemical data was collected at varying intervals up to an elapsed time of 1038 days. The data has been used to estimate the mass, mean position vector, and covariance tensor of the bromide plume. A number of interpretive steps was necessary to compute these plume moments. First, the spatially scattered data were interpolated onto a

regular grid, with the interpolator selected on the basis of a cross-validation criterion. The moment estimates then could be calculated readily, although it was recognized that the interpolation procedure can lead to bias in the moment estimates. For this reason, reduced-bias, jackknifed estimates of the moments, as well as confidence intervals for these estimates, were derived. The total plume variance also was estimated with the jackknife method. The latter results were compared with the prediction of a recent stochastic model developed by Dagan (1988). When this model was applied in a completely predictive mode, a remarkably good estimate of the total plume variance resulted. (Author's abstract)

Concentrations of the trace elements Al, Cd, Pb, Mn and Zn were determined in water and sediments of six acidic clear-water lakes (pH 3.6-6.2) in northwestern New Jersey. Levels of Al, Pb and Zn in the water column were sharply elevated in the most acidic lakes, with values similar to acidified systems elsewhere. Seasonal fluctuations occurred, with Pb displaying peak concentrations in all lakes during the fall sampling period. Analyses of core samples of lake sediment indicated that while Pb concentrations exhibited a typical sharp increase in most recent sediments, Cd and Zn levels in the upper layers were substantially lower than values reported for similar systems elsewhere. As expected, Mn concentrations generally decreased in the upper sediment layers in the acidic lakes, while Al varied dramatically between systems. (Author's abstract)

Descriptors: *Chlorinated hydrocarbons, *Fish, *Path of pollutants, *Pesticide residues, *Polychlorinated biphenyls, Abu Qir Bay, Chemical analysis, Coastal waters, DDD, DDE, DDT, Egypt, Endosulfan, Fate of pollutants, Gas chromatography, Lake Idku, Lake Maryut, Lakes, Marine environment, Methoxychlor, Tilapia, Tissue analysis.

Residues of polychlorinated biphyenyls (PCBs) and organochlorine chemicals were analyzed by capillary gas chromatography in five fish species (Pagellus erythrinus, Sargus vulgarius, Siganus rivulatus, Sphyraena sphyraena and Trigia hirundo) from Abu Qir Bay as well as in Tilapia species from Idku and Maryut lakes in Alexandria, Egypt. Total DDT and PCBs were the most predominant contaminants occurring in the muscle tissue of all fish samples. Remarkable variations in the concentrations of PCBs were noted among the species, and the concentrations of total DDT were higher than that of PCBs in all fish species. Elevated PCB concentrations were observed in muscle tissue of S. vulgarius from Abu Qir Bay, and in Tilapia zillii from Forn El-Gieraia, Maryut lake. Also, variations were found in the relative proportions of p,p'-DDT, p,p'-DDD and p,p'-DDE in all fish samples. The results revealed an increase in chlorinated hydrocarbons with increase in body size and fat content. Neither alpha-endosulfan nor beta-endosulfan was detected in fish from Abu Qir Bay; however, only alpha-endosulfan was detected in trace amounts in Tilapia species from Idku and Maryut lakes. With the exception of S. vulgarius, mirex and methoxychlor occurred in low levels in all other fish species. From a public health standpoint, residue levels of organochlorines and PCBs in all fish samples analyzed are considerably lower than known tolerance levels; however, there is an increasing need for monitoring of these contaminants to insure the protection of food sources. (Author's abstract)

EFFECTS OF ENVIRONMENTAL PARAMETERS ON THE ELIMINATION OF CADMIUM BY EASTERN OYSTERS, CRASSOSTREA VIRGINICA.
National Marine Fisheries Service, Charleston, SC. Southeast Fisheries Center.
F. M . Van Dolah, T. C. Siewicki, G. W. Collins, and J. S. Logan.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 6, p 733-743, November 1987. 2 fig, 6 tab, 27 ref.

Descriptors: *Cadmium, *Heavy metals, *Humic acids, *Oysters, *Path of pollutants, *Salinity, *Temperature effects, *Toxicology, Animal metabolism, Cadmium radioisotopes, Chelating agents, Chemical analysis, Copper, Fate of pollutants, Iron, Laboratory methods, Magnesium, Trace metals, Zinc.

Laboratory studies were conducted to test the effects of salinity, humic acid and temperature on the rate of elimination of Cd109 from laboratory-dosed juvenile oysters, Crassostrea virginica. After 140 days, oysters maintained at 34 parts per thousand (ppt) salinity retained 67% of the Cd109 dose (CPM), oysters in 20 ppt salinity retained 72% and those in 6 ppt salinity retained 80%. The presence of humic acid in 14 ppt salinity water enhanced the amount of Cd109 eliminated in 140 days relative to oysters in control tanks without humic acid; oysters exposed to 10 parts per million (ppm) humic acid retained 65%, oysters exposed to 1 ppm humic acid retained 67%, controls retained 72%. Temperature had a significant effect on the rate of Cd elimination. Oysters held at 28 degrees and 20 ppt for 28 days retained 75%, oysters at 20 degrees and 20 ppt retained 81% and those at 12 degrees and 20 ppt retained 88% of Cd109 dose. The effects of a strong Cd-chelator, ethylenediamine tetraacetic acid-sodium salt (EDTA) were compared with those of the relatively weaker chelator, humic acid, on the rate of Cd elimination by oysters. No difference was observed between the two chelators over a 28 day depuration period. Cadmium concentrations were monitored in the water and Cd, Cu, Zn, Mg and Fe concentrations were determined in the animals on the final day of the studies. Tissue Zn concentrations behaved similarly to tissue Cd concentrations, while Cu and Fe behaved oppositely from those of Cd and Zn. Mg correlated with salinity. Particle clearance assays were performed to determine if the rate of filtration by the oysters held in each of the test treatments correlated with the rates of Cd depuration. No direct correlation was observed. (Author's abstract)

A rapid filter-lift assay was developed for identification of bacteria capable of degrading ganophosphorus pesticides. Filter pads impregn ed with parathion were applied to the surface plates containing potential parathion-degrad colonies. Positive colonies capable of convert parathion to 4-nitrophenol attain a visible yell coloration after 30 min of exposure; however, identification of selected individuals was diffi when large numbers of colonies were screened a single plate. An enhancement of this screer method was achieved with the use of UV-pho raphy, which allowed for the detection of a su mutant or cured colony among 500 parath degrading colonies per plate. In addition, it possible to detect a single parathion-degra colony among 10000 non-degrading colonies plate. The efficiency of the technique was vali ed with a parathion-degrading strain of Pse monas diminuta from which phenotypically n tive isolates were selected, subjected to pla isolation, evaluated for detoxifying activity, tested by a battery of microbiological criteri confirm the parental strain phenotype. All productive colonies were identical to the par strain except for the lack of detoxifying capal and the loss of a large plasmid found in the p tal strain. (Author's abstract)

25 to 30% of all United States publicly-treatment works (POTW) discharges enter s and coastal waters. An expert system has eveloped to model the fate and transport of als discharged from POTWs into estuaries. POTW has been classified as one of four primary, trickling filter, lagoon and activsludge in terms of treatment level. The system is designed to calculate concentrations under 7-d 10-year low flow, summer low flow and annual mean flow conditions. To account for varying mixing characteristics and salinity distributions observed in a given estuary, the system includes one-dimensional and two-dimensional (longitudinal and vertical) mass transport algorithms. To date, the modeling framework has been applied to nine estuaries. For validation purposes, biochemical oxygen demand (BOD) concentrations are also predicted based on industrial as well as municipal organic carbon loads. In several estuaries, predicted in-stream BOD levels have been compared to measured BOD data resulting in successful model validation. The validated models are then used to predict linear alkylbenzene sulfonate (LAS) concentrations in estuaries. These LAS concentrations are found to be less than 20 micrograms/L in these estuaries under the three flow conditions. (Author's abstract)

GEOCHEMISTRY OF BATCH-EXTRACT WATERS DERIVED FROM SPOIL MATERIAL COLLECTED AT THE CORDERO COAL MINE, POWDER RIVER BASIN, WYOMING.
Geological Survey, Cheyenne, WY. Water Resources Div.
D. L. Naftz.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 87-4200, 1990. 58p, 21 fig, 14 tab, 26 ref.

Descriptors: *Geochemistry, *Mine wastes, *Model studies, *Powder River Basin, *Water pollution effects, *Water pollution sources, *Water quality, *Wyoming, Coal mining, Mineralogy.

Batch-mixing experiments to evaluate postmining water quality at the Cordero Mine were conducted by the U.S. Geological Survey during 1984 to 1985. Contact of groundwater from the spoil aquifer with fresh spoil material caused only small changes in major-element concentrations and in pH, unless sulfide oxidation or contact with soluble salts, such as epsomite, occurred. In contrast, large changes in major-element concentration resulted when water from the coal aquifer contacted the spoil material. Only three of seven reaction models considered to explain the water quality changes during the batch-mixing experiments were consistent with the thermodynamic and mineralogical data. The three models used to account for the observed water quality changes derived potassium from potassium feldspar; magnesium from chlorite or epsomite or both; sodium from cation exchange and halite; chloride from halite; silica from potassium feldspar and chlorite; sulfate from gypsum, or epsomite or both, and carbon from carbon dioxide. In general, water quality samples obtained from the batch-mixing experiments using water from the coal aquifer had smaller major-ion concentrations than the actual water quality in the spoil aquifer. These differences can be explained by the limited amount of efflorescent salt dissolution and volume of water used in the experiments. Correction ratios calculated for these experiments may be applied to batch-mixing experiments at other mines in the area, to predict postmining water quality. (USGS)

HYDROLOGY OF GOAT LAKE WATERSHED, SNOHOMISH COUNTY, WASHINGTON, 1982-87.
Geological Survey, Tacoma, WA. Water Resources Div.
N. P. Dion, J. C. Ebbert, J. E. Poole, and B. S. Peck.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 88-4235, 1989. 44p, 11 fig, 8 tab, 36 ref.

Descriptors: *Acid rain, *Goat Lake, *Mountain lakes, *Washington, *Water quality, Acid rain effects, Acidification, Alkalinity, Water pollution sources, Watersheds, Yield.

The Goat Lake watershed in Snohomish County, Washington, functions as an 'experimental watershed' for long-term studies to determine the effects of acidic precipitation on water resources. Data have been collected there by the U.S. Geological Survey since 1982. The watershed is in a wilderness area of the Cascade Range and is downwind of an industrial and urban area that produces chemical compounds found in acidic precipitation. The lake is considered sensitive to acidic inputs from atmospheric deposition and streamflow. The mean annual discharge of the Goat Lake outflow is 35 cu ft/sec; precipitation on the watershed is calculated to be about 170 in/yr. The inflow to Goat Lake is sufficient to replace the entire contents of the lake basin on an average every 21.5 days, or 17 times/year. Water in Goat Lake, and that of the inlet and outlet, is of low ionic strength and of calcium-bicarbonate type. The lake, although considered oligotrophic, is sufficiently deep to stratify thermally, and summer dissolved-oxygen concentrations in the hypolimnion are depressed. Even though alkalinity and specific conductance at Goat Lake are in the range considered sensitive to acidic inputs, the pH of water in the lake has consistently ranged from 6.1 to 7.2, indicating that the lake is not acidified at this time. U. S. GEOLOGICAL SURVEY APPLIED RESEARCH STUDIES OF THE CHEYENNE RIVER SYSTEM, SOUTH DAKOTA: DESCRIPTION AND COLLATION OF DATA, WATER YEARS 1987-88.
Geological Survey, Rapid City, SD. Water Resources Div.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Open-File Report 89-580, 1990. 145p, 9 fig, 52 tab.

Descriptors: *Cheyenne River, *Hydrologic data, *Mine wastes, *Path of pollutants, *South Dakota, *Water pollution sources, *Water quality, Adsorption-desorption, Analytical techniques, Biology, Sediment chemistry.

The Cheyenne River System in western South Dakota has been impacted by the discharge of about 100 million metric tons of gold-mill tailings to Whitewood Creek near Lead, South Dakota. In April 1985, the U.S. Geological Survey initiated an extensive series of research studies to investigate the magnitude of the impact and to define important processes acting on the contaminated sediments present in the system. The report presents all data collected during the 1987 and 1988 water years for these research studies. Some of the data included have been published previously. Data collected in the 1985 and 1986 water years have been published in a companion report (U.S. Geological Survey Open-File Report 88-484). Hydrologic, geochemical, and biologic data are available for sites on Whitewood Creek, and the Belle Fourche and Cheyenne Rivers. Data complexity varies from routine discharge and water-quality to very complex energy-dispersive x-ray analysis. Methods for sample collection, handling and preservation, and laboratory analysis are also presented. No interpretations or complex statistical summaries are included. (See also W89-08390) (USGS)

SOURCE, EXTENT, AND DEGRADATION OF HERBICIDES IN A SHALLOW AQUIFER NEAR HESSTON, KANSAS.
Geological Survey, Lawrence, KS. Water Resources Div.
C. A. Perry.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 90-4019, 1990. 24p, 10 fig, 7 tab, 14 ref. USGS Project No. KS151.

Descriptors: *Degradation, *Fate of pollutants, *Groundwater pollution, *Herbicides, *Kansas, *Path of pollutants, *Water pollution sources.

Atrazine, alachlor, cyanazine, metolachlor, and metribuzin were detected in water from a domestic well completed in a shallow aquifer underlying the Harvey County Experiment Field near Hesston, Kansas. The study described in this report investigated the source, extent, and degradation of these five herbicides. Hydrogeologic analysis of the site enabled estimation of the degradation half-lives of the herbicides in the saturated zone. The most probable source of the contamination was backsiphonage or spillage of herbicides from a sprayer tank into a trench backfilled with sand. The herbicides moved downgradient to the domestic well and then moved into the aquifer via the annular space in the well. Once in the aquifer, the contaminants remained nearly stationary with very little lateral movement away from the point of injection. Decreases in herbicide concentrations were caused mainly by degradation of the parent compounds and to a lesser degree, by extensive pumping of the well. Estimated herbicide degradation half-lives in the saturated environment were 1,000 days for atrazine, 400 days for alachlor, 250 days for cyanazine, 350 days for metolachlor, and 350 days for metribuzin. The herbicides will likely be eliminated from the soil and groundwater at the experiment field by continued natural degradation at the land surface and by degradation in and continued pumping of water from the aquifer. Pumping will remove any degradation products as well as the remaining parent compounds. (USGS)

GEOHYDROLOGY AND GROUNDWATER GEOCHEMISTRY AT A SUB-ARCTIC LANDFILL, FAIRBANKS, ALASKA.
Geological Survey, Anchorage, AK. Water Resources Div.
J. S. Downey, and P. O. Sinton.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 90-4022, 1990. 25p, 21 fig, 2 tab, 11 ref.

Descriptors: *Alaska, *Geohydrology, *Landfills, *Path of pollutants, *Water pollution sources, Biological processes, Cold regions, Water chemistry.

The Fairbanks-North Star Borough, Alaska, landfill is located on silt, sand, and gravel deposits of the Tanana River flood plain, about 3 miles south of the city of Fairbanks water supply wells. The landfill has been in operation for about 25 years in this sub-arctic region of discontinuous permafrost. The cold climate limits biological activity within the landfill with corresponding low gas and leachate production. Chloride concentrations, specific conductance, water temperature, and earth conductivity measurements indicate a small plume of leachate flowing to the northwest from the landfill. The leachate remains near the water table as it flows northwestward toward a drainage ditch. Results of computer modeling of this local hydrologic system indicate that some of the leachate may be discharging to the ditch. Chemical data show that higher-than-background concentrations of several ions are present in the plume. However, the concentrations appear to be reduced to background levels within a short distance along the path of groundwater flow from the landfill, and thus the leachate is not expected to affect the water supply wells. Descriptors: *Congo, *Developing countries, *Domestic wastes, *Groundwater pollution, *Human diseases, *Wastewater pollution, *Water pollution sources, Aquifer characteristics, Path of pollutants, Sanitation, Water supply, Wells.

Sanitary and social conditions prevailing in the outskirts of Brazzaville (Congo) are a cause of concern and are linked to the poor quality of drinking water. In areas not fitted with a water supply system, waterborne diseases such as amoebiasis, bacillary dysentery, and diarrhea are the prime causes of morbidity. A fact-finding operation was initiated in 1985 to determine the effects of pollution on the underground water surrounding Brazzaville. Thirty water wells (sources and fountains included) were selected and checked. Type of well, location of well, design parameters, past and present use of the well, and the possibility of obtaining data were determined in a preliminary phase of the project. These wells are regularly checked and physical, chemical, and bacteriological analyses of their water are conducted. Industrial waste is unknown around Brazzaville; agriculture is confined to non-intensive gardening and chemical fertilizers and pesticides are used rarely. Pollution of domestic origin is the most important source and accounts for 70% of the cases of contamination of the aquifer as revealed by the preliminary results of this study. Water presents a crucial problem in Burkina Fas for two reasons: its scarcity and its unsanitar condition in both the towns and the countrysid One of the consequences of development of urba centers is the significant production of water fc domestic and industrial consumption. The contam nation of aquatic systems that results from this indicated by modification of physical, chemica and biological characteristics and by the frequenc of illnesses resulting from poor water quality. Th phenomenon was studied in Burkina Faso throug observations of the evolution of pH in the Riv We in Bobo-Dioulasso, its ionic composition, ar the productivity of reservoir waters in Ouagado gou. Overall, the mineral and organic contributic of wastes in the surface waters in Ouagdougou ar Bobo-Dioulasso seems to favor development aquatic life and because of it, a certain self-purific tion of these waters occurs. In the long term. Th concentration of pollution would endanger the bi logical equilibrium. The surface waters in tow could become a favorable medium for concentr tion and expansion of serious microbial illness because these waters are often used directly f domestic consumption. WATER QUALITY IN RESERVOIRS: T EFFECT OF INFLOWING POLLUTION.
Vyzkumny Ustav Vodohospodarsky, Pra (Czechoslovakia).
E. Kockova.
Ergebnisse der Limnologie ERLIA6, Vol. 33, 3, p 827-829, 1990. 2 tab, 3 ref.

Descriptors: *Czechoslovakia, *Limnology, *R ervoirs, *Water pollution sources, *Water qua Ammonium, Biological oxygen demand, Dissol oxygen, Lentic environment, Organic matter, P toplankton.

In the Brno Water Research Institute, Czecho vakia, research in surface water pollution has b directed towards two localities. The first syste reservoirs is that of Nove Mlyny situated at confluence of the Dyje, Jihlava and Svratka ri in the South Moravian region. The inflow water of the Dyje is contaminated with high le of organic compounds as indicated by BOD5, also with mineral components. The water c contains minimal concentrations of disso oxygen (DO) or even no oxygen at all. P contamination is responsible for the constant ence of ammonium ion. The BOD5 value aver 23 mg/L in 1986; in the last 5 years the loa inflowing water fluctuated between 15 an tons/day BOD5. The oxygen regime is influe by many other factors such as the intensive gr of phytoplankton, resulting in the oversaturati water during the summer days. Overnight a the morning the phytoplankton draws on oxygen until its concentration reaches zero. O to the small depth the stagnant water ha oxygen at all in the bottom zone, and in r years this has often led to fish kills. The inco contamination, sedimentation of the or matter, and other effects have a negative imp the upper third of the reservoir, which is dor ed by the decrease in DO. In the second loc the Dalesice reservoir, the inflowing water

river Jihlava contains high concentrations of DO, with an average BOD5 of 10 mg/L; during 1980-83 the load of the inflow-profile fluctuated between 3.35 and 9.32 tons/day BOD5. Although this reservoir is substantially less contaminated than the Nove Mlyny reservoir, the general trend of the water quality has not been satisfactory, especially in relation to the oxygen regime. Neither the motion of the water surface nor turbine and pumping operations have substantially affected the oxygen balance of the whole water column. Consequently, in this reservoir, especially in the summer, the surface water is oversaturated (owing to biological activity) in the vertical direction; at the same time bottom water at depths of 5 m to 74 m contain less than 4 mg/L of DO. The low DO concentrations are documented by average values of the yearly measurement of vertical layers in both reservoirs. (Sand-PTT)

ORGANIC SOLVENT-SOLUBLE CONTENTS OF NICKEL AND COBALT IN SOME ALGAE.
Mainz Univ. (Germany, F.R.). Inst. fuer Anorganische Chemie und Analytische Chemie.
R. Pfarr, and R. Neeb.
Naturwissenschaften NATWAY, Vol. 77, No. 8, p 383-384, August 1990. 1 tab, 5 ref.

Descriptors: *Algae, *Chemical analysis, *Chemical speciation, *Laboratory methods, *Nickel, *Path of pollutants, *Solvents, Chlorophyta, Cobalt, Germany, Heavy metals, Organic solvents, Trace metals.

Heavy metal speciation studies have gained increased importance, especially in view of the need to assess the biological behavior of these metals. Algae samples, mostly Cladophora and Ulothrix, were collected in the Rheinhessen region near Mainz and the total amounts of Ni and Co were determined by adsorption voltammetry with dimethylglyoxime. The solvent-soluble amounts of Ni and Co were measured for a non-polar solvent (hexane) as well as a weakly polar one (chloroform). About 0.1-1.7% of the total Ni and 0.1-2.0% of the total Co are extracted into the solvents with the fraction of metal soluble in the weakly polar solvent higher than the fraction soluble in the nonpolar solvent. A correlation between the total amount present and that extracted was not found. Treatment of the algae prior to the analytical procedure, e.g., with 0.02 molar EDTA per 1 or 0.1 molar HCl/L, decreased the total metal content to a degree which varied from sample to sample, but did not noticeably influence the fraction of metal which dissolved in the organic solvents. (Hoskin-PTT)

USE OF CLUSTER ANALYSIS TO DEFINE PERIODS OF SIMILAR METEOROLOGY AND PRECIPITATION CHEMISTRY IN EASTERN NORTH AMERICA: PART I. TRANSPORT PATTERNS.
Michigan Univ., Ann Arbor. Dept. of Atmospheric, Oceanic and Space Sciences.
M. E. Fernau, and P. J. Samson.
Journal of Applied Meteorology JAMOAX, Vol. 29, No. 8, p 735-750, August 1990. 12 fig, 3 tab, 23 ref.

Descriptors: *Acid rain, *Chemistry of precipitation, *Cluster analysis, *Meteorology, *North America, *Path of pollutants, *Regional Acid Deposition Model, *Weather patterns, Climatology, Computer programs, Model studies, Rainfall distribution, Synoptic analysis, Weather data collections.

An aggregation approach is desirable in order to use results from the Regional Acid Deposition Model to determine seasonal or annual deposition loads in eastern North America. The complexity and number of computations involved in the Regional Acid Deposition Model make it costly to directly model long-term deposition by repeated simulation of episodes of several days duration. Cluster analysis has been used sparingly in synoptic climatological and air pollution applications. Cluster analysis was applied to transport vectors, derived from three years of daily backwards trajectories, in order to define a synoptic climatology of representative three-day periods of air mass movement. The resulting clusters represent groups whose mean air mass transport fields were statistically different from one another and corresponded to the types of high and low pressure patterns seen on daily weather maps. Seasonal differences were evident in the frequency of occurrence of each cluster. The clusters were relatively insensitive to changes in number of sites or years used; however, different clustering methods yielded somewhat different clusters. Ward's hierarchical grouping method yielded clusters with more or less equal numbers while other methods tended to produce one large cluster and a series of outlier clusters. Cluster analysis was useful in the computer-assisted classification of spatial patterns of weather data and should be considered for use along with more widely used synoptic climatological tools such as principal component analysis. (See also W91-02410) (Mertz-PTT)

USE OF CLUSTER ANALYSIS TO DEFINE PERIODS OF SIMILAR METEOROLOGY AND PRECIPITATION CHEMISTRY IN EASTERN NORTH AMERICA: PART II. PRECIPITATION PATTERNS AND POLLUTION DEPOSITION.
Michigan Univ., Ann Arbor. Dept. of Atmospheric, Oceanic and Space Sciences.
M. E. Fernau, and P. J. Samson.
Journal of Applied Meteorology JAMOAX, Vol. 29, No. 8, p 751-761, August 1990. 8 fig, 5 tab, 19 ref.

Descriptors: *Acid rain, *Chemistry of precipitation, *Cluster analysis, *Meteorology, *North America, *Path of pollutants, *Weather patterns, Climatology, Computer models, Deposition, Model studies, Rainfall distribution, Regional Acid Deposition Model, Synoptic analysis, Water pollution sources, Weather data collections.

The spatial precipitation patterns and wet deposition chemistry associated with transport-derived clusters were examined to determine whether representative meteorological events conducive to high acid deposition could be identified. These representative events could be used in aggregation schemes to extend the results of the episode-based Regional Acid Deposition Model to determine seasonal or annual deposition loads in eastern North America. Cluster analysis has been little used in synoptic climatological and air pollution applications to date. Cluster analysis was applied to transport vectors, derived from three years of daily trajectories arriving at monitoring sites, in order to define a synoptic climatology of representative three-day periods of air mass movement. The resulting clusters were successful in defining wet, dry, polluted and nonpolluted clusters, as shown by the spatial patterns of median deposition and by statistical testing. The highest pollutant depositions over the widest areas resulted from mean transport patterns with large areas of slow air mass movement over the regions of high sulfur emissions and which were frequently persistent over several periods or followed persistent clusters. There was a large amount of overlap among the chemistry distributions and large variation within most of the clusters. Seasonal differences exist within each cluster, with sulfur deposition within a given cluster generally being higher in the warmer months. Cluster analysis was shown to be useful in the computer-assisted classification of spatial patterns of weather and pollution data. (See also W91-02409) (Mertz-PTT)

GROUNDWATER MONITORING: VOLATILE ORGANIC CHEMICALS BENEATH UNSEWERED SUBDIVISION.
Wisconsin Univ.-Eau Claire. Dept. of Geology.
J. R. Tinker.
Journal of Environmental Health JEVHAH, Vol. 53, No. 2, p 26-28, September/October 1990. 5 fig, 12 ref.

Descriptors: *Drinking water, *Groundwater pollution, *Path of pollutants, *Public health, *Volatile organic compounds, *Water pollution sources, Septic wastewater, Tetrachloroethylene, Water quality standards, Well data, Well water, Wisconsin.

Water supply wells in Mill Run Subdivision, Eau Claire County, Wisconsin were sampled for volatile organic chemicals. Mill Run was selected because on-site septic-tank, soil-absorption systems within the subdivision had increased the nitrate-nitrogen levels in the water supply wells to an average of 11.1 mg/L and volatile organic chemicals occur in septic system cleaners and other household products. Fifty-nine water samples from 26 water-supply wells in and adjacent to the unsewered subdivision were analyzed. Three samples from two wells had 1.3 to 3.1 micrograms/L of tetrachloroethylene, but the source of the tetrachloroethylene could not be determined from available data. The enforcement standard in Wisconsin for tetrachloroethylene is 1 microgram/L. The Wisconsin Department of Natural Resources notified in writing the residents of the duplexes served by Wells 21 and 18 of the results of the volatile organic chemicals sampling and the enforcement standard for tetrachloroethylene. Residents were warned not to drink the water. (Mertz-PTT)

MERCURY ACCUMULATION IN RELATION TO SIZE AND AGE OF ATLANTIC HERRING (CLUPEA HARENGUS HARENGUS) FROM THE SOUTHWESTERN BAY OF FUNDY, CANADA.
Guelph Univ. (Ontario). Dept. of Zoology.
B. M. Braune.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 3, p 311-320, May 1987. 3 fig, 7 tab, 46 ref. Natural Sciences and Engineering Research Council of Canada Strategic Grant No. G0304 (1980-83).

Descriptors: *Bioaccumulation, *Canada, *Fish, *Herring, *Mercury, *Path of pollutants, *Water pollution effects, Aquatic environment, Bay of Fundy, Chemical analysis, Correlation analysis, Data interpretation, Fate of pollutants, Marine animals, Marine environment, Marine pollution, Metabolism, Model studies, Muscle, Water analysis, Zooplankton.

Relationships between weight, length or age, and total mercury concentration in Atlantic herring were investigated. In addition, the applicability a model for total mercury accumulation developed for freshwater fish to a sampled population of marine fish, specifically Atlantic herring, was also determined. Measured muscle and whole fish total mercury concentrations showed significant positive correlations with age, weight and length, in order of decreasing correlation. Within herring age classes, however, muscle and whole fish mercury concentrations showed significant negative correlations with weight and length due to a growth dilution effect in 1 and 2 year old herring. However, a positive correlations with weight and length was demonstrated in 3 to 5 year old fish. A bioenergetic-based pollutant accumulation model was used to describe total mercury accumulation for the commercially valuable Atlantic herring aged 3 to 5 years. The predicted values fell within one standard deviation of the measured annual body burdens for the herring. (Author's abstract)

DDT CONTAMINATION OF BENTHIC MACROINVERTEBRATES AND SEDIMENTS FROM TRIBUTARIES OF WHEELER RESERVOIR, ALABAMA.
Auburn Univ., AL. Dept. of Fisheries and Allied Aquacultures.
E. C. Webber, D. R. Bayne, and W. C. Seesock.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 18, No. 5, p 728-733, September 1989. 1 fig, 4 tab, 18 ref.

Descriptors: *Alabama, *Benthic environment, *Benthic fauna, *Bottom sediments, *DDT, *Food chains, *Macroinvertebrates, *Path of pollutants, *Reservoirs, *Sediment analysis, *Sediment contamination, *Streams, Benthos, Bottom sampling, Ecosystems, Trophic level, Water pollution sources.

Residues of 1,1,1-trichloro-2,2-bis(p-chlorophenyl) ethane (DDT) were measured quarterly during 1983-1984 in bottom sediments and benthic macroinvertebrates from heavily contaminated sections of Huntsville Spring Branch (HSB) and Indian Creek (IC), backwater streams on Wheeler Reservoir (Alabama). Bottom muds from both channel and overbank locations contained mean concentrations of DDTR (DDT and its metabolites) ranging from 12 to 2,730 ppm (dry weight). Sediment DDTR were highest in HSB at stations closest to the original DDT source. Stations in IC, downstream from HSB, had progressively lower DDTR as distance from the DDT source increased. Macroinvertebrate DDTR measured from several stations suggested bioaccumulation of residues mainly through food webs. However, at the most contaminated locations, substrate and mode of life appeared to override trophic level effects in determining DDTR in the benthos. There is apparently an upper limit to the amount of DDTR these organisms usually accumulate. For example, detritivore DDTR from channel sediments at two stations just downstream from the DDT source averaged 2,370 ppm and 96 ppm, respectively. Benthic macroinvertebrates in the highly contaminated sediments of HSB and IC apparently acquire DDTR from water, sediments, and food. (Author's abstract)

DDT compounds (p,p' and o,p' isomers of DDT and metabnolites DDE and DDD were studied in fish, water, and bed sediments from the Yakima River drainage in Washington State. p,p'-DDE was the predominant compound in fish and the only DDT compound detected in water from the main stem of the river. However, concentrations of p,p'-DDT predominated in water and bed sediments from Yakima tributaries identified as current sources of DDT compounds. These data suggest DDT is extremely persistent in Yakima basin soils. Data compiled by the U.S Geological Survey and U.S. Fish and Wildlife Service illustrated a historical trend toward decreasing concentrations of DDT compounds in water and fish from the main stem of the Yakima River. A positive correlation between runoff and water concentrations of chlorinated pesticides has been demonstrated in a number of investigations. Results from this study showed DDT compounds were routinely detectable in several Yakima River tributaries during the irrigation season, but could not be detected in any tributary after diversions for irrigation ceased. EFFECT OF URANIUM MINE TAILINGS ON RADIONUCLIDE CONCENTRATIONS IN LANGLEY BAY, SASKATCHEWAN, CANADA.
Environmental Protection Service, Regina (Saskatchewan).
D. T. Waite, S. R. Joshi, and H. Sommerstad.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 3, p 373-380, May 1988. 1 fig, 5 tab, 28 ref.

Descriptors: *Lake Athabasca, *Mine wastes, *Path of pollutants, *Radioisotopes, *Uranium radioisotopes, *Water pollution sources, Acid mine drainage, Bioaccumulation, Calcium, Canada, Conductivity, Ions, Langley Bay, Magnesium, Sulfates, Water chemistry, Water pollution.

From 1955 to 1964 the Gunnar Uranium Mine (Canada) produced approximately 8000 tons of uranium oxide and about 5,000,000 tons of waste rock tailings. Large quantities of fine tailings material washed into Langley Bay, a shallow bay opening onto Lake Athabasca. The initial movement of tailings into Langley Bay occurred suddenly, as a result of the demolition of a retaining dam. This material consisted of a slurry of untreated, acidic wastes produced by the sulfuric acid extraction process used by the mine. Following this initial event, effluent from the process continued to transport materials in the bay until mine closure in 1964. Runoff from the uphill tailings continues to move various metals into Langley Bay. The sediment data showed concentrations of radionuclides and some heavy metals to be much higher in Langley Bay than in the uncontaminated control area. The tailings content of the sediments in Langley Bay had significantly affected the water chemistry. The water of the two control sites was of low conductivity, Ca(2+), HCO3(-) type, typical of shield areas. Sites overlying tailings showed marked differences in both major and minor components. Conductivities were higher as a result of increases in Ca(2+), Mg(2+) and SO4(2-), probably derived from the CaSO4 and MgSO4 precipitates reported to be in the tailings. Concentrations of uranium found in Langley Bay water fell within the 0.5-200 microgram/L range reported for American rivers. Concentrations of 226Ra and 210Pb at some sites were higher than those reported for other northern Canadian waters above contaminated sediments. These radionuclides were available for uptake by the resident biota. The northern pike and whitefish populations of Langley Bay contained higher body burdens of radionuclides than those from uncontaminated control areas. (Mertz-PTT)

INORGANIC POLLUTION OF THE MAN-MADE LAKES OF WADI EL-RAIYAN AND ITS IMPACT ON AQUACULTURE AND WILDLIFE OF THE SURROUNDING EGYPTIAN DESERT.
Cairo Univ., Giza (Egypt). Faculty of Agriculture.
M. A. Saleh, M. A. Saleh, M. M. Fouda, M. A. Saleh, and M. S. A. Abdel Lattif.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 3, p 391-403, May 1988. 4 fig, 8 tab, 45 ref.

Descriptors: *Aquaculture, *Deserts, *Reservoirs, *Water pollution effects, *Water pollution sources, Agricultural runoff, Ammonia, Bioaccumulation, Cadmium, Carbonates, Copper, Cyanide, Egypt, Halogens, Heavy metals, Iron, Lead, Manganese, Mercury, Nitrates, Nitrites, Phosphates, Selenium, Silicates, Sulfates, Sulfites, Thiocyanate, Water pollution, Zinc.

El-Raiyan lakes were created as a reservoir for agricultural drainage wastewater in the Western Desert of Egypt. The project was started in 1968 and has been operating since 1973. Physical and chemical properties of water from 17 sampling stations in the lakes and in the springs of the surrounding deserts were monitored every three months during the years 1984 and 1985. Concentrations of metals (cadmium, copper, iron, lead, manganese, mercury, selenium, and zinc) and of inorganic anions (sulfate, sulfite, sulfide, nitrate, nitrite, ammonia, cyanide, thiocyanate, halogens, carbonate, silicate, and phosphate) were generally lower than those reported for other lakes of Egypt which are used as wastewater reservoirs. The concentrations of metals and inorganic anions in water varied according to the distance from the origin of the lakes, depth, and seasons of the year. Concentrations of heavy metals in fish and in selected wildlife fauna and flora of the surrounding deserts were also determined. Animals living near the lakes had much higher concentration of heavy metals, particularly lead, mercury, and cadmium than animals of the same species collected further away from the lakes. High rate of evaporation may cause concentrations of heavy metals to soon reach dangerous levels. This may effect the utilization of the lake for fish production and may also pollute groundwater of the nearby springs and be transferred through the food chain to wildlife of the area. The use of biological filters and/or growing grass on the sand dunes may be used to clean up heavy metals from the water. (Mertz-PTT)

TIGRIS-EUPHRATES DELTA: A MAJOR SOURCE OF PESTICIDES TO THE SHATT AL ARAB RIVER (IRAQ).
Basrah Univ. (Iraq). Dept. of Environmental Marine Chemistry.
A. A. DouAbul, H. T. Al-Saad, A. A. Al-Timari, and H. N. Al-Rekabi.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 3, p 405-41

May 1988. 4 fig, 5 tab, 33 ref.

Descriptors: *Bioaccumulation, *Chlordane, *DDD, *DDE, *DDT, *Deltas, *Endrin, *Halogenated pesticides, *Heptachlor, *Path of pollutants, *Shatt Al-Arab River, *Water pollution sources, Arid lands, Euphrates River, Iraq, Mussels, Pesticide residues, Pesticides, River sediments, Tigris River, Water pollution.

Organochlorine pesticides were determined in the Tigris-Euphrates-Shatt al-Arab Delta by high resolution gas chromatography. Mean concentrations of pesticides in the dissolved form were 98 ng/L p,p'-DDE (2,2-bis(p-chlorophenyl)-1,1-dichloroethylene); 8 ng/L o,p'-DDD (2,2-bis(p-chlorophenyl)-1,1-dichloroethane); 28 ng/L p,p'-DDD; 16 p,p'-DDT (2,2-bis(p-chlorophenyl)-1,1,1-trichloroethane); 30 mg/L aldrin; 66 ng/L dieldrin; 57 ng/L cis-chlordane; 15 ng/L trans-chlordane and 10 ng/L heptachlor. Mean particulate concentrations were 76 microgram/kg dry weight for p,p'-DDE; 67 microgram/kg p,p'-DDT; 154 microgram/kg endrin; 11 microgram/kg cis-chlordane; and 68 microgram/kg heptachlor. Partitioning of dissolved pesticides was evident along the Shatt al-Arab River, which was reflected by significantly higher levels of particulate species down river. Residues of p,p'-DDE; p,p'-DDD; p,p'-DDT; endrin and dieldrin were confirmed in sediments from this river; however, DDD was confined to the anoxic sub-surface layers only. Absorbing pesticides from both water and suspended particulate matter, Shatt al-Arab mussels had mean residue concentrations of 43 microgram/kg wet weight p,p'-DDD; 12 microgram/kg aldrin; 24 microgram/kg dieldrin; 6 microgram/kg cis-chlordane and 5 microgram/kg trans-chlordane. The euphrates River was the major source of pesticides in the dissolved form, while the Tigris River contributed pesticides mainly in the particulate form to the Shatt al-Arab River. The sediment of this river was the largest reservoir of organochlorine pesticides, where more than 80% of the studied contaminants reside. (Author's abstract)

LONG-TERM MONITORING OF POLYCHLORINATED BIPHENYLS IN THE HUDSON RIVER (NEW YORK) USING CADDISFLY LARVAE AND OTHER MACROINVERTEBRATES.
New York State Dept. of Environmental Conservation, Albany. Div. of Water.
M. A. Novak, A. A. Reilly, and S. J. Jackling.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 6, p 699-710, November 1988. 6 fig, 5 tab, 11 ref.

Descriptors: *Bioassay, *Bioindicators, *Hudson River, *Monitoring, *Polychlorinated biphenyls, *Water pollution sources, Caddisflies, New York, Water pollution.

Polychlorinated biphenyl (PCB) contamination of the Hudson River occurred over a period of nearly 50 years, via discharges by capacitor manufacturing plants in Hudson Falls and Fort Edward, New York. Concentrations of PCBs in the Hudson River were monitored from 1978 through 1985, by chromatographic analysis of the tissue residues of hydropsychid caddisflies and the contents of artificial substrate samplers. For both means of assessment, levels of Aroclor 1016 and Aroclor 1254 were positively correlated. Temporally, PCB concentrations decreased at all sampling stations from 1978 to 1980, but increased and remained stable from 1981 through 1985. Spatially, PCB levels as measured by artificial substrate samplers, decreased along the length of the river. Spatial trends in caddisflies were not as consistent as those of the artificial substrate samplers; in 6 of the 8 years sampled, there was no significant decrease in PCB concentrations in caddisflies from the point of discharge of the contaminant to the most downstream sampling site. (Mertz-PTT)

POLYCHLORINATED BIPHENYL CONGENERS IN SEDIMENTS, PLANKTON, MOLLUSCS, CRUSTACEANS, AND EEL IN A FRESHWATER LAKE: IMPLICATIONS OF USING REFERENCE CHEMICALS AND INDICATOR ORGANISMS IN BIOACCUMULATION STUDIES.
Amsterdam City Environmental Health Research Lab. (Netherlands).
R. van der Oost, H. Heida, and A. Opperhuizen.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 6, p 721-729, November 1988. 3 fig, 5 tab, 36 ref.

Descriptors: *Bioaccumulation, *Biological magnification, *Food chains, *Monitoring, *Path of pollutants, *Polychlorinated biphenyls, Fish, Lakes, Macroinvertebrates, Plankton, The Netherlands, Water pollution.

The concentrations of six polychlorinated biphenyl (PCB) congeners in sediments and four classes of biota species of the aquatic food chain were investigated in a freshwater lake near Amsterdam, The Netherlands. Despite the low concentrations of the contaminants in the sediment, significant amounts of PCBs were found in plankton, macro-invertebrates and fish. The composition of the PCB mixtures found in the various organisms cannot be explained in terms of simple partitioning of the PCB congeners between sediment, water, and organisms. In addition to bioconcentrations, it is likely that biomagnification via consumption of contaminated food also contributed significantly to the total PCB concentrations. This is most pronounced for the higher trophic food-chain organisms. Studying bioaccumulation processes by monitoring just one type of organism is probably not very suitable, due to the pronounced differences in accumulation patterns demonstrated for the different organisms. In addition, significant differences were found in the accumulation of the six PCBs in the various biotic samples. This indicates that the fate of the mixtures of PCBs is determined by the fate of the individual congeners and therefore cannot be monitored in terms of total PCBs concentrations. (Author's abstract)

SPATIAL DIFFERENCES AND TEMPORAL TRENDS OF ORGANOCHLORINE COMPOUNDS IN BIOTA FROM THE NORTHWESTERN HEMISPHERE.
Statens Livsmedelsverk, Uppsala (Sweden). Food Research Dept.
O. Andersson, C. E. Linder, M. Olsson, L. Reutergardh, and U. B. Uvemo.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 6, p 755-765, November 1988. 4 fig, 3 tab, 37 ref.

Descriptors: *Biological magnification, *DDD, *DDE, *DDT, *Halogenated pesticides, *Path of pollutants, *Pesticide residues, *Polychlorinated biphenyls, *Spatial distribution, *Temporal distribution, Animals, Arctic zone, Baltic region, Birds, Chlordane, Fate of pollutants, Fish, Polychlorinated camphenes, Seals.

Tissues of animal species from various trophic levels in the northwestern hemisphere were collected and analyzed for the presence of polychlorinated camphenes (PCC, for example toxaphene), DDT and its metabolites DDD and DDE and PCB (polychlorinated biphenyl) to elucidate differences in geographical distribution, biomagnification and temporal trends. Many of the samples were also analyzed for the presence of chlordane. The previously achieved knowledge of DDT and PCB contamination was used as a yardstick for characterizing the exposure regime of the other organochlorine compounds. No pronounced geographical differences were found for polychlorinated camphenes when comparing animals from the Arctic region with corresponding species in the Baltic, while PCB, DDD and DDE showed definite spatial differences. The highest concentrations of DDD, DDE and PCB were found in fish predators, such as raptorial birds and seals, from the Baltic. Polychlorinated camphenes levels in fish exceeded levels of DDD, DDE and PCB in the North Atlantic and the polychlorinated camphenes levels in Swedish fish were as high or higher than the DDD and DDE levels. While the DDD, DDE, and PCB levels for all trophic levels ranged from 0.14-990 mg/Kg fat, the corresponding range for polychlorinated camphenes was only 0.33-17 mg/kg. This indicated less biomagnification of polychlorinated camphenes and/or a more effective metabolism of polychlorinated camphenes, compared with DDD, DDE, and PCB, at high trophic levels. The levels of DDD, DDE, and PCB is Swedish fish and birds showed a decrease during the late seventies and the beginning of the eighties. For the polychlorinated camphene levels, however, no distinct trends could be discerned during the same period in any of the areas studied. (Author's abstract)

Journal of Hydraulic Engineering (ASCE) JHEND8, Vol. 116, No. 10, p 1158-1179, October 1990. 17 fig, 1 tab, 15 ref.

Descriptors: *Coastal waters, *Diffusion, *Dispersion, *Ocean dumping, *Path of pollutants, *Water currents, California, Eddy diffusion, Oceanography, Outfall, Theoretical analysis, Tides, Turbulent flow, Waste disposal.

Oceanographic drogue and current meter studies were performed in the coastal waters of southern California. The transport and dispersing properties of the oceanographic currents were evaluated over diurnal periods and related to extant theories of diffusion and dispersion in coastal waters. The measurements provided useful results concerning Lagrangian and Eulerian estimates of turbulent diffusivity. In particular, they show the importance of regarding diffusivity as an ensemble average property of the turbulent flow field, and that great care is necessary in applying the concept to single realization studies. It was shown that under some tide conditions significant negative diffusivities are possible. Furthermore, coastal motions at this location were very coherent up to scales of 4-5 km, at which point they become rapidly dispersive. The results provide information of value in the design of ocean disposal systems. (Author's abstract)

FREE AMMONIA AND TOXICITY CRITERIA IN A POLLUTED URBAN LAKE.
Upstate Freshwater Inst., Inc., Syracuse, NY.
S. W. Effler, C. M. Brooks, M. T. Auer, and S. M. Doerr.
Research Journal of the Water Pollution Control Federation JWPFA5, Vol. 62, No. 6, p 771-779, September/October 1990. 7 fig, 3 tab, 40 ref.

Descriptors: *Ammonia, *Eutrophication, *Lake restoration, *Path of pollutants, *Urban areas, *Water pollution control, *Water quality, Algal growth, Hydrogen ion concentration, Monitoring, New York, Onondaga Lake, Seasonal variation, Toxicity, Wastewater pollution.

The distribution of free ammonia in Onondaga Lake, New York, a polluted urban lake, was documented for the spring-to-fall interval of 1988. Free ammonia levels were compared with national criteria set to protect fish from toxic effects. Nearly continuous contravention of the national chronic

toxicity criteria for free ammonia for salmonid and nonsalmonid fish, at all depths, and infrequent contravention of the national acute toxicity criterion for nonsalmonids in the upper waters was documented. The occurrence of particularly high concentrations of free ammonia was associated with increases in pH, driven by high levels of algal growth. A major reduction (>60%) in the concentration of total ammonia in the epilimnion of the lake is necessary to remediate the lake's free ammonia problem. This would require a major reduction (>50%) in the load presently received from the adjoining wastewater treatment plant. This remediation effort should be integrated with ongoing programs, focusing on the lake's problem of excessive algal growth, because of the impact of algal photosynthetic activity on levels of free and total ammonia in the lake. The Fluminense coastline between the cities of Rio de Janeiro and Cabo Frio includes numerous eutrophic lagoons. A recent increase in urbanization has resulted in uncontrolled effluent discharges into some of these lagoons. An evaluation was made of the environmental quality with respect to nutrients, heavy metals, and organic micropollutants at Lagoa de Guarapina, a tropical eutrophic lagoon of Rio de Janeiro State, Brazil. Sampling for dissolved inorganic nitrogen species was conducted over an annual cycle (winter 1985 to 1986) at four stations in the lagoon. In addition, samples for particulate organic carbon and nitrogen were collected at the central station in the lagoon. Trace metal analyses were performed on surficial sediments at five stations and their vertical distribution was assessed on a separate sediment core from the central lagoon station. The cations exchange capacity, organic matter content and heavy metals manganese, chromium, zinc and lead generally decrease from the fluvial to the lower estuarine station, with maximum values at the central lagoon station and decrease sharply towards the lower portion, close to the tidal inlet. Nickel and copper, however, remained fairly constant. Concentrations of nutrients and heavy metals in the lagoon and its tributaries were low, closely resembling natural conditions. However, lead formed the exception, and its presence in conjunction with detectable concentrations of organic micropollutants suggest that minor pollution effects are occurring via atmospheric inputs. PERSISTENCE OF SPILLED CRUDE OIL IN A TROPICAL INTERTIDAL ENVIRONMENT.
Puerto Rico Univ., Mayaguez. Dept. of Marine Sciences.
J. E. Corredor, J. M. Morell, and C. E. Del Castillo.
Marine Pollution Bulletin MPNBAZ, Vol. 21, No. 8, p 385-388, August 1990. 2 fig, 2 tab, 15 ref.

Descriptors: *Degradation, *Fate of pollutants, *Mangrove swamps, *Marine pollution, *Oil spills, *Path of pollutants, *Puerto Rico, *Sediment contamination, Biodegradation, Hydrocarbons, Intertidal areas, Oil, Oil pollution, Sediment analysis, Tropical regions.

In the last few decades, two major tanker spills of crude oil have occurred off the southern coast of Puerto Rico; that of the Argea Prima in 1962 and the Zoe Colocotronis in 1977. As a contribution to the CARIPOL program for petroleum pollution research and monitoring in the Caribbean region, the vertical distribution of hydrocarbons in a core from sediments was documented. Intertidal sediments at Bahia Sucia, on the southwest coast of Puerto Rico contain discreet subsurface layers of petrogenic hydrocarbons. The uppermost of these layers contains petroleum contaminants in concentrations above 100 mg/g and is most probably attributable to the 1977 spill. A deeper layer containing a less concentrated load of petroleum hydrocarbons may correspond to the spill of 1962. Sediments above, between and below these two layers present low concentrations of typically biogenic hydrocarbons. Although petroleum released to the sea in tropical environments generally suffers rapid degradation, petroleum contaminants reaching intertidal sediments may exhibit long-term persistence. In the case of mangrove-lined intertidal environments, rapid burial coupled to the well-documented bacteriostatic nature of mangrove tannins result in a dramatic decrease in degradation rates of petroleum hydrocarbons in these environments. Persistence of these substances may well have subsequent long-term deleterious effects upon the mangroves themselves as well as the complex plant and animal communities associated with the mangroves. TRACE METALS IN THE SEVERN ESTUARY: A REAPPRAISAL.
Water Research Centre, Medmenham (England).
S. C. Apte, J. M. Gardner, A. M. Gunn, J. E. Ravenscroft, and J. Vale.
Marine Pollution Bulletin MPNBAZ, Vol. 21, No. 8, p 393-396, August 1990. 2 fig, 2 tab, 10 ref.

Descriptors: *England, *Estuarine environment, *Heavy metals, *Path of pollutants, *Trace metals, *Water pollution sources, Arsenic, Cadmium, Chromium, Copper, Distribution patterns, Lead, Nickel, Salinity, Severn River Estuary, Water quality, Zinc.

The Severn estuary is the largest estuary in the United Kingdom. The salinity/concentration profiles of seven dissolved trace metals, i.e., copper (Cu), nickel (Ni), cadmium (Cd), lead (Pb), chromium (Cr), zinc (Zn), and arsenic (As), in the Severn estuary were reported. The metal concentrations observed in this study were considerably lower than those reported in previous work. Despite known inputs of metals through industrial and waste discharges, river inputs play an important part in the estuarine profiles. For Cu, Ni and Zn, riverine inputs appear to be the main source of metals. The profiles of Cd, Cr and As appear to be dominated by point source discharges in mid-estuary. Lateral heterogeneity is small, except in the vicinity of industrial outfalls. In spite of this, quite large between-day variations in dissolved metal concentrations were observed in the upper estuary. Chromium was the only metal not showing between-day variability. Saline end member concentrations were consistent with ranges quoted for the European coastal shelf area. This survey suggests that atmospheric deposition is far less important, at least as a contributor to concentrations of dissolved metal, though its influence on particulate metal may still be significant. (VerNooy-PTT)

HYDROCARBON CONCENTRATIONS IN SEDIMENTS AND ANIMAL TISSUES FROM THE COASTAL WATERS OF KARACHI.
Karachi Univ. (Pakistan). Inst. of Marine Biology.
S. Durrani, and S. A. Siddiqui.
Marine Pollution Bulletin MPNBAZ, Vol. 21, No. 8, p 397-399, August 1990. 2 fig, 1 tab, 9 ref.

Descriptors: *Coastal waters, *Marine pollution, *Oil pollution, *Pakistan, *Path of pollutants, *Water quality, Fish, Hydrocarbons, Oil, Oil refineries, Oil spills, Oysters, Sediment analysis, Sediment contamination, Tissue analysis.

Preliminary data is presented on the present levels of petroleum hydrocarbon contamination in coastal waters of Karachi (Pakistan) resulting from the exploitation, refining and routine handling of petroleum. Surface sediment samples in triplicate and subtidal samples were collected from the intertidal zone during low tide from Korangi Creek and Hawks Bay and from Manora Channel. Oysters (Crassostrea rivularis and Perna viridis) and fish (Mugil sp. and Acanthopagurus sp.) were also collected. Extracted aliphatic hydrocarbons were analyzed by gas chromatography. In marine sediment a range of hydrocarbons (n-C7 to n-C19) were detected. Levels found in the sediments were 0.0 to 0.16 ng/g for n-C19 and 0 to 0.24 ng/g for n-C16. Hydrocarbon peaks were not observed in the tissues of Perna viridis and fish from any locality. The coastal waters of Karachi seem to discourage persistence of oil pollution due to the availability of light, temperatures characteristic of tropical areas, and well oxygenated water. (VerNooy-PTT)

OIL POLLUTION IN THE SOUTHERN ARABIAN GULF AND GULF OF OMAN.
Institute of Oceanography and Fisheries, Alexandria (Egypt).
H. I. Emara.
Marine Pollution Bulletin MPNBAZ, Vol. 21, No. 8, p 399-401, August 1990. 6 fig, 2 tab, 11 ref.

Descriptors: *Arabian Gulf, *Data collection, *Marine pollution, *Oil pollution, *Water quality, *Water sampling, Distribution patterns, Hydrocarbons, Oil, Oil spills, Path of pollutants.

Results are presented from the winter cruise (February to 3 March, 1987) carried out in the southern Arabian (Persian) Gulf and the gulf of Oman, as well as previous work in the Northwestern Arabian Gulf in 1984 to 1986. Surface and subsurface (10 to 200 m) samples were taken. Kuwait crude oil was used as standard with detection limits of 1 microgram/L. Petroleum hydrocarbons in surface water varied from 4.6 to 2 micrograms/L in the southern Arabian Gulf compared with 4.4 to 63 micrograms/L in the Gulf of Oman. 54% of the analyzed samples contained less than 16 micrograms/L. Starting from the Qatar waters, the petroleum levels generally showed decrease in an eastward direction until Sharjah the United Arab Emirates water. The vertical profile of petroleum hydrocarbons was nearly homogeneous due to vertical mixing characteristic of winter season. Data from 1984 to 1987 were examined. Excluding the highly polluted stations, 1987 levels of petroleum hydrocarbons are exceptionally high in comparison with other areas in the world oceans. When the concentrations all stations including the highly contaminated

were considered, the mean values decrease from 1984 to 1987 indicating that during 1984 to 1985 the Gulf water was affected by oil spills due to the Iraq-Iran war. The average concentration of petroleum hydrocarbons in the Gulf area varied from 15 to 65.2 micrograms/L during the years 1987 and 1984, respectively. The annual contribution of petroleum hydrocarbons that fluxed from the Arabian Gulf to the Gulf of Oman during 2987 is 23% of the annual fluxes recorded in 1984. (VerNooy-PTT)

LOADING OF WATER AND SOIL BY POLLUTANTS IN SHELBY COUNTY.
Christian Brothers Univ., Memphis, TN.
K. Madhavan.
Journal of the Tennessee Academy of Science TASAG, Vol. 65, No. 4, p 121-128, 1990. 2 fig, 7 tab, 5 ref.

Descriptors: *Path of pollutants, *Pesticides, *Pollutant load, *Soil contamination, *Water pollution sources, Air pollution, Aldrin, Atrazine, Bacteria, DDT, Heptachlor, Herbicides, Memphis, Organic compounds, Pollutant identification, Shelby County, Surface runoff, Suspended solids, Tennessee, Wet deposition.

A study was undertaken to indicate the possible extent of pollution of the surface soil in and near Memphis. Since rain carries surface and atmospheric pollutants into the runoff, water samples were collected and analyzed for pollutants at different times during and between rainfall events. Only one site was studied in a residential area and only one site was studied near a chemical plant, to give an idea of the extent of pollution under differing environmental conditions. The results presented are site specific and vary with other factors such as weather, rainfall rate, rainfall intensity, previous rainfall conditions, and number of household pets in the neighborhood. For the residential site, the amounts of various chemicals present were below the surface water criteria for pesticides in public water supplies. Results obtained in the industrial site are also site specific since the extent of pollution mainly depends on the proximity of the study site from the chemical industries. (Lantz-PTT)

Descriptors: *Chemical analysis, *Heavy metals, *Lakes, *Path of pollutants, *Trace metals, *Water pollution sources, Air pollution, Aluminum, Copper, England, Iron, Lead, Manganese, Pollution load, Wastewater disposal, Wet deposition, Windermere, Zinc.

Dissolved (<0.45 microm) and particulate concentrations of Fe, Mn, Al, Cu, Pb, and Zn were measured at intervals of 2-6 weeks in rivers, sewage effluents, atmospheric deposition, and surface lake waters within the Windermere (U.K.) catchment, over a two year period. Factor analysis revealed a number of geochemical associations: a large proportion of the particulate Fe, Al, Pb, and Cu appears to be associated with detrital minerals and organic materials in the rivers, sewage effluents, and atmospheric deposition; redox processes, probably occurring higher in the catchment, have an appreciable influence on the riverine concentrations of dissolved Fe and Mn, particulate Mn, and to a lesser extent particulate Fe and Zn; pollution terms account for most of the variance of dissolved Fe, Cu, Pb, and Zn, and particulate Cu, Pb, and Zn in the sewage effluent and atmospheric deposition data sets; and an association in the rivers of dissolved Al and Zn concentrations with discharge is probably related to catchment soil processes. Mass balances were determined for the metals, including a detailed assessment of the errors involved. An imbalance was apparent between the inputs and the outputs (flushing and sedimentation), probably due to the underestimation of particulate loads in the rivers. Fe, Mn, and Al were predominantly (> 90%) supplied by rivers, while Cu, Pb, and Zn received significant inputs from direct atmospheric deposition and sewage discharges. The residence times of the dissolved metals in Windermere were in the order: Cu > Zn > Pb, Fe, a sequence consistent with observations in various alpine lakes. More than 50% of the dissolved inputs of each metal was retained in the lake, except for Cu, which appeared to show a small net loss from the lake. (Author's abstract)

Available from the National Technical Information Service, Springfield, VA 22161. NOAA Technical Memorandum ERL PMEL-92, July 1990. 59 p, 12 fig, 15 tab, 55 ref, append.

Descriptors: *Estuaries, *Model studies, *Path of pollutants, *Puget Sound, Data interpretation, Hydrologic models, Runoff, Salinity, Strait of Juan de Fuca.

The increasing urbanization of the Puget Sound region is resulting in concern about the long-term circulation of the Sound and its relationship to the transport and dispersal of pollutants. As part of a study of this problem, a project was undertaken to calculate systematically the annual mean runoff, salinity and transport of the Sound. Puget Sound was modeled as a branched system of two-layered advective reaches separated by mixing zones. Fresh-water and salt-water provide convenient tracers to calculate the annual mean layer transports. The technique used historical records (1951-1956) of runoff and salinity which were analyzed with the aid of modern (principally in the 1970s) current meter records to provide the appropriate mass conserving landward-flowing and seaward-flowing layer salinities for each reach. For the first time long-term transports have been estimated simultaneously for the entire Strait of Juan de Fuca/Puget Sound system. With few exceptions the inferred transports agree well with estimates derived from scattered, shorter duration current observations. Uncertainties in the transports are estimated from uncertainties in the runoff, velocity profiles and salinities. The analyzed runoff and salinity data sets and the inferred transports provide a foundation for applying the reflux theory to Puget Sound. (Lantz-PTT)

Descriptors: *Acid rain, *California, *Mountain lakes, *Path of pollutants, *Water pollution sources, Acetates, Ammonium, Crystal Lake, Hydrogen, Hydrogen ion concentration, Nitrates, Pear Lake, Ruby Lake, Seasonal variation, Sierra Lake, Snow, Sulfates, Topaz Lake.

Four high elevation lake watersheds in the Sierra Nevada were studied from October 1986 through June 1988. Researchers measured wet deposition, lake outflow, and lake chemistry and physics at these sites using the mass balance approach to relate the effect of wet deposition on lake and stream water chemistry. Crystal and Ruby Lakes, located on the eastern slope of the Sierra, and Topaz and Pear Lakes, located on the western slope in Sequoia National Park, were found to be dimictic. Major solute concentrations in the subsurface reached a minima during the latter part of snowmelt. Near-bottom concentrations of these solutes generally had less seasonal variation and were generally higher than subsurface values. Mean snow depth and chemical concentrations were similar for the winters of 1986-87 and 1987-88 at all watersheds. Volume-weighted mean pH ranged from 5.3 to 5.5, with the dominant ions being hydrogen, ammonium, acetate, nitrate and sulfate. Wet deposition as mixed rain and snow occurring between May and October can deliver more solutes to the watersheds than winter snows. (Author's abstract)

Descriptors: *Fate of pollutants, *Organic pollutants, *Path of pollutants, *Sediment chemistry, *Sediment-water interfaces, *Sorption, Anions, Benzene, Cations, Chlorinated hydrocarbons, Germany, Hydrogen ion concentration, Methane, Temperature effects.

Sorption of selected organic contaminants by aquatic sediments was examined. The sorbates used were dichloro methane, trichloro methane, 1,1,1-

trichloro ethane, trichloro ethene, tetrachloro ethene and 1,2-, 1,3-, as well as 1,4-dichloro benzene. For comparison parathion and hexachloro benzene were also used in the experiments. The sediments were taken from a freshwater tidal marsh of the Elbe river near the city of Hamburg. Sorption equilibria were reached in less than one hour. Sorption was generally reversible and was adequately described by linear partition coefficients. Sorption increased with increasing organic carbon content of the sediments. The sorption coefficients of a compound based on the organic carbon fraction, Koc, however, were almost equal for all sediments tested. Sorption experiments under varied conditions had the following results: (1) Sorption decreased with increasing temperature. The sorption enthalpies are about 8.6 kJ/mol for all sediments and dichlorobenzenes; (2) The pH has no effect on the sorption of the dichlorobenzenes; (3) Increasing the salinity enhances the sorption; (4) Acetic acid, NTA, as well as methanol introduced to concentrations up to some g/L, showed no effect; and (5) Detergents caused a marked desorption at concentrations above their critical micelle concentrations. The anionic compound TBS, however, enhanced the sorption of an acidic sediment (pH 3.5), when the concentration of the detergent was increased. The cationic TCAB exhibited at concentrations somewhat below the critical micelle concentration a marked increase of the sorption of DCB, Parathion and HCB. These phenomena can be explained by the surface charge characteristics of the sediment particles. (Author's abstract)

OIL SLICK SIZES AND LENGTH OF COASTLINE AFFECTED: A LITERATURE SURVEY AND STATISTICAL ANALYSIS--FINAL REPORT.
Minerals Management Service, Los Angeles, CA. Pacific OCS Region.
G. G. Ford.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-204648/AS. Price codes: A03 in paper copy, A01 in microfiche. Report No. MMS 85-0105, October 1985. 37p, 7 fig, 5 tab, 68 ref.

Descriptors: *Coastal waters, *Oil pollution, *Oil spills, *Path of pollutants, *Statistical analysis, Mathematical equations, Model studies, Prediction, Regression analysis.

An historical and statistical analysis of the size of oil slicks at sea and the length of coastline affected by oil slicks which come ashore was undertaken. A total of 21 incidents which included descriptions of slick sizes at sea, and 39 incidents which included descriptions of the amount of coastline oiled were located in the literature. Only incidents for which estimates of oil outflow were available were accepted. Stepwise multiple linear regression was used to determine which factors were the most accurate predictors of slick size and coastline affected. A regression model was developed which could account for 90.1% of the variation in slick size based on spill volume, age of spill, wind speed, and wave height. A simplified equation based only on spill volume and age--assuming the average wind and wave conditions in the Southern California Bight--was presented. The variation in slick sizes which was not explained by the regression model was used to construct a model to estimate the probability that a spill of a given volume and age would reach a particular size. Stepwise regression was also used to build a predictive model of the length of coastline affected by a spill which comes ashore. Only two variables, spill volume and latitude, contributed significantly to the prediction of coastal oiling. These two variable accounted for 64.8% of the variation in the length of coastline affected. As with slick sizes, a model based on the unexplained variance in length of coastline affected was constructed to estimate the probability that a spill of a given volume would affect a given length of coastline. Descriptors: *Agricultural runoff, *Groundwater quality, *Nonpoint pollution sources, *Path of pollutants, *Surface-groundwater relations, *Water pollution sources, Adsorption-desorption, Advection, Aeration zone, Groundwater management, Groundwater movement, Infiltration, Solute transport, Solutes, Water quality management, Water resources management.

The impact of agricultural activities on water quality is a problem of growing interest. Different substances that are soluble in water are spread over large areas and may leach through the unsaturated zone into the groundwater, following groundwater movement, eventually reaching surface water and public supply wells. Decisions on appropriate administrative and technical measures are based on the assessment of potential hazards that may arise due to groundwater quality changes. In order for the potential hazard to be assessed in an objective manner, the uncertainty in predictions of regional solute transport needs to be quantified. The effect of field-scale infiltration on surface water quality was analyzed. A hypothetical example, where solute leaches from a heterogeneous field and is transported through the aquifer to surface water, was examined. Both conservative and reactive solutes were considered, where the assumed reaction was first order non-equilibrium sorption-desorption. The influence of variability in the parameters that control advection in the unsaturated zone decreases with the distance from the source area. This effect is more pronounced for a conservative than for a reactive solute. The effect of sorption-desorption in the unsaturated zone on regional movement of solute is to decrease the expected peak concentration and reduce the influence of field heterogeneity. The results on regional solute transport are primarily qualitative and provide an indication of the uncertainty that may be expected in field applications. (See also W91-02672) (Fish-PTT)

When a convective-dispersive phenomenon of groundwater pollutants is analyzed, its mechanism should be regarded as stochastic, because of many uncertainties in the interaction between pollutant and flow. A method based on the Fourier series expansion and the extended Kalman filter has been developed to identify the parameters of a one-dimensional constant coefficient stochastic convective-dispersive equation and to predict the concentration distribution of groundwater pollutants. This method was compared with two synthetically generated concentration distributions: one with constant physical parameters and the other with spatial change in the physical parameters. The results obtained showed that the proposed method would be able to predict the concentration distribution and identify the parameters accurately. (See also W91-02672) (Fish-PTT)

INFLUENCE OF PRECIPITATION ON THE QUALITY OF KARST GROUNDWATER IN INDUSTRIAL ZONES.
Belgrade Univ. (Yugoslavia). Faculty of Mining and Geology.
N. Kresic, P. Papic, and R. Golubovic.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 153-159, 4 fig, 2 tab, 3 ref.

Descriptors: *Acid rain effects, *Air pollution effects, *Groundwater quality, *Karst hydrology, *Water pollution sources, Acid rain, Correlation analysis, Geohydrology, Groundwater management, Hydrogen ion concentration, Industrial wastes, Mineralization, Nitrates, Precipitation, Regression analysis, Serbia, Spring water, Sulfates, Water quality management, Water resources management, Yugoslavia.

Complex hydrogeological researches on karst aquifers in western Serbia, Yugoslavia, conducted for water supply purposes, found an increased content of some hydrochemical components in groundwater. The groundwater quality in an important karst aquifer in the vicinity of Valjevo, a large industrial center in western Serbia, has worsened during the last few years. An increased content of nitrates and sulfates is caused by acid rain. Its influence was analyzed daily for two years, with particular attention being paid to the regimes of nitrates, sulfates, pH values, and mineralization both in precipitation and spring discharge, depth of precipitation, and spring discharge. Connections between these elements were established through correlation and regression analysis. It was concluded that further industrialization without preventing the emission of pollutants might cause an exceedance of the permitted limits in the near future. Since the early 1980s, monitoring studies for pesticide residues in groundwater have been conducted in several countries. In the Netherlands, pesticide admission requires the estimation of their leaching potential to groundwater. To assess the risk of groundwater pollution by pesticides in the Netherlands, the occurrence and behavior of selected pesticides in the upper groundwater was investigated. On land with potatoes, maize, and flower bulb culture, and on uncropped land, filter tubes were placed for periodic sampling and analysis. So far, 21 different organic compounds have been

letected in groundwater as a consequence of the pplication of pesticides. The highest concentra- ions found involve persistent admixtures and de- omposition products, which are more polar and hus more mobile in the soil than the parent com- ound. Apart from the pesticides, decomposition roducts and admixtures are a threat to ground- vater quality and drinking water supply. (See also V91-02672) (Author's abstract)

multidisciplinary approach was adopted to ne pollution plume development in a sand aqui- at a landfill site. Aquifer parameters, water ity changes, and plume development were de- ined through detailed hydrogeological investi- ons and regular hydrochemical monitoring and physical surveys. Hydraulic conductivities esti- d from grain size analyses were confirmed by nates obtained from a tracer test and gave groundwater velocities in the range 60-100 m/year. This is in agreement with the rate of plume advancement. Data collected from the field studies were used in a groundwater flow and solute transport model to predict the rate of pollution plume development and provide a basis for aquifer management in the vicinity of the site. Further work is in progress to integrate the microscale variations of the hydraulic conductivity, as indicated by the tracer test, to estimate better the critical parameters of the plume scale dispersivity. Although apparently a uniform sand, the aquifer underlying the landfill shows significant microscale variability, particularly of the hydraulic conductivity, which suggests variable pollution velocities. It is, therefore, critical to appraise properly the likelihood of such variability in any remedial work at a landfill site. (See also W91-02672) (Fish-PTT)

DECOMPOSITION AND ELIMINATION OF TYPICAL POLLUTANTS FROM SANITARY LANDFILLS IN POROUS AQUIFERS.
Technische Univ. Braunschweig (Germany, F.R.). Leichtweiss-Inst. fuer Wasserbau und Grundbau.
P. Spillmann.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 227-233, 3 fig, 2 ref.

Descriptors: *Fate of pollutants, *Groundwater pollution, *Groundwater quality, *Landfills, *Path of pollutants, *Sanitary landfills, Aquifers, Atrazine, Bacteria, Chemical oxygen demand, Decomposition, Germany, Groundwater management, Landfill covers, Leachates, Leaching, Lindane, Loam, Pathogens, Pesticides, Sand, Simazine, Solute transport, Water quality management, Water resources management.

In the past, sanitary landfills were not sealed or drained and it is not absolutely certain that a modern sealing would be completely impermeable today and in the future. Groundwater pollutants caused by sanitary landfills are currently being investigated in defined artificial aquifers in an interdisciplinary research project in Germany. In order to measure the transport and the elimination of the substances polluting the groundwater, the following method was selected: a defined quantity of leachate from a refuse dump is added to an artificial aquifer where there is a definite flow path. The load of the added leachate is then compared to the load of the outflow. The leachate both from a freshly built landfill and from an old, biologically decomposed dump is investigated under parallel conditions. In the same way, the effect of a porous covering layer of sand is compared with a barely permeable covering layer of compacted loam. This gives a total of four parallel artificial aquifers, each of which permits investigations to be made concerning the transport and decomposition of pollutants from dumps and sanitary landfills. In addition to the leachate, germs, 2-3-dichlorphenol, Simazine, Atrazine, Lindane, and Coli bacteria are added. Initial results of the research show that the remaining load-constant chemical oxygen demand is converted further into substances similar to natural substances and that the organic substances of the leachate from refuse encourage the decomposition of various synthetic organic compounds. There is virtually no pollutant or solute in groundwater which will not eventually undergo chemical transformation including adsorption, reaction, speciation, complexation, etc. A correct interpretation of concentration data in groundwater requires a coupled model of transport and chemical processes. Coupling of non-trivial chemical models to transport models results in systems of non-linear partial differential equations and algebraic equations. The split-operator method has been used in their numerical solution. Two applications of chemical models coupled to transport were examined: a cation (heterogeneous fast reaction) and a nitrate system (a heterogeneous slow reaction). For field applications there is a competition between transport and chemistry which can only be evaluated with three-dimensional or horizontally two-dimensional models: a breakthrough of nitrate in a well can be caused either by nitrate passing by the spill or by nitrate being no longer used up by microbial activity in the spill itself. Coupled models allow these effects to be considered and can therefore be useful in the design of an in situ remediation. Ambiguity in identifying the model parameters can be diminished if the parallel transport of several components is observed and interpreted. These models may well be used for purposes such as testing of hypotheses, gaining insight into system behavior, and interpretation of column experiments. (See also W91-02672) (Fish-PTT)

IDENTIFICATION OF UNSATURATED SOLUTE TRANSPORT PARAMETERS.
Pontificia Univ. Catolica de Chile, Santiago. Faculty of Engineering.
R. Abeliuk.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 261-270, 1 fig, 3 tab, 14 ref.

Descriptors: *Hydrologic models, *Model studies, *Path of pollutants, *Solute transport, Algorithms, Convection, Dispersion, Flow models, Groundwater management, Hydrodynamics, Hydrologic data, Numerical analysis, Optimization, Parametric hydrology, Soil contamination, Soil moisture, Unsaturated flow, Water quality management, Water resources management.

Although a number of analytical solutions of partial differential equations have been developed to describe one-dimensional solute transport, these solutions are only applicable to specific cases where simplifying assumptions can be made. A general model of solute transport must include the equations for flow and solute transport, with terms included as appropriate to account for physical, chemical, or biological interactions of the solute with the soil environment. The problem of parameter identification is probably the major restriction on the practical application of comprehensive numerical models of unsaturated solute transport. An optimization algorithm with two different forms of the objective function was used to estimate the parameters governing the convection-dispersion equation for the transport of solutes under unsaturated flow conditions. The results show that at least two forms of the coefficient of hydrodynamic dispersion produce identical performance when used to simulate the transient transport of a nonreactive solute in a column of unsaturated soil, confirming that the form of this coefficient is ambiguous when identified from transient moisture content/solute profiles, and hence indicating that interpretation of analytical forms from experimental data must be carried out with great caution. When a large number of parameters are estimated the optimization technique generates various parameter sets that reproduce the calibration data adequately for both types of objective function. However, when the number of parameters decreases, the technique identifies unique parameter values. In all cases, however, the estimated param-

eter sets are robust in prediction. (See also W91-02672) (Fish-PTT)

To protect groundwater quality, it must be understood how contaminants migrate in groundwater systems, and it must be known what and how much information is needed to predict such migration. In real situations under irregular aquifer geometry, the controlling factors on the propagation of a plume may not be the dispersion parameters, but the flow field. A three-stage modeling approach that produces a fully three-dimensional plume was developed to compare the effects due to dispersion to those due to the flow field. The propagation of the well-monitored Borden (Toronto, Canada) contaminant plume was simulated in three dimensions. The results show that plume propagation is strongly controlled by the three-dimensional flow field. The most relevant parameters for the simulation were found to be those that govern the three-dimensional flow field, namely the stratigraphy, the aquifer geometry, the hydraulic conductivity, and the flow boundary conditions. To verify the prediction of asymmetry, the aquifer stratigraphy and recharge pattern should be confirmed by independent measurements. Dispersion, although important, plays a less controlling role. The implication on the decision-making process in groundwater resource investigations is that primary data acquisition should focus on defining the three-dimensional groundwater flow system. In recent years contamination of groundwater by industrial chemicals, especially petroleum products and halogenated solvents, has become a problem of major concern. A three-dimensional model of the advective transport of volatile organic contaminants in the gaseous phase of the unsaturated zone has been developed and tested against selected analytical solutions. The model accounts for the evaporation of contaminants from a pure liquid surface, partitioning of a contaminant from an aqueous solution and the adsorption/desorption of organics with soil particle surfaces. The results predict the concentrations of volatile organics throughout the soil profile allowing the user to estimate the amounts of hydrocarbons leaving the soil via volatilization. The model can aid the analysis, design, and operation of remediation efforts using an In Situ Volatilization (ISV) system. The ISV is used to prevent volatile organic compounds from migrating with infiltrating water through the vadose zone to the underlying groundwater table. (See also W91-02672) (Author's abstract)

Groundwater quality and quantity in the Chino basin, California, have been seriously affected by agricultural, industrial, and municipal developments during the past few decades. Increasing water demands have caused overdraft of the groundwater while indiscriminate disposal of agricultural and dairy wastes have contributed to the downgrading of the quality of the groundwater. To remedy the overdraft problem, imported water from the State Water Project is to be used in conjunction with the local groundwater through artificial recharge. However, there is currently no plan for controlling and reducing high levels of nitrate in the aquifer. A numerical simulation model was used to study the hydraulic response of the aquifer to the recharge program and to analyze the feasibility of recharge basins. The model simulates two-dimensional regional changes in the water table over time. Also, a mass transport model was used to simulate the movement and fate of nitrate in the aquifer considering the recharge program with the existing rate of waste disposal. Results of the water quality model show that the recharge program using the proposed recharge facilities would not alter the nitrate levels. However, if the existing recharge basins in the southern portion of the Chino basin were to be used, the nitrate levels would be expected to decrease considerably or not increase at the current rate over the next 15-20 years. APPLICATION OF GROUNDWATER MODELLING IN WATER RESOURCES MANAGEMENT IN DENMARK.
Miljoestyrelsen, Copenhagen (Denmark).
M. Dyhr-Nielsen.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 559-570, 6 ref.

Descriptors: *Aquifer management, *Denmark, *Groundwater management, *Groundwater resources, *Irrigation effects, *Model studies, *Streamflow depletion, *Surface-groundwater relations, *Water resources management, *Water supply development, Agricultural chemicals, Case studies, Environmental policy, Groundwater pollution, Hydrologic models, Leachates, Management planning, Minimum flow, Nitrates, Path of pollutants, Research priorities, Water pollution control.

With a water supply almost entirely dependent on groundwater, Denmark has extensive experience in management and control of groundwater resources. Natural recharge is mostly sufficient to satisfy the water supply needs except in the most populated areas around major cities like Copenhagen. However, a policy of water resource management based on environmental impacts has made stream depletion the most important constraint for water development. To achieve rational estimates of the potential effects of groundwater developments on streamflow, extensive investigations and model tools have been developed on the initiative of the National Agency of Environmental Protection. Also the more recent water resources problems associated with agricultural nitrate pollution and leaching of chemical wastes has led to the initiation of major interdisciplinary research programs. Developments in Danish water resource management have progressed from a case-by-case basis to comprehensive pollutant control programs. Some major research projects initiated in connection with important management issues include the determination of streamflow depletion, nitrate pollution from agriculture, and reclamation of groundwater polluted by chemical wastes. As western European sulfur emissions continue to decline following peak levels in the 1970's, interest is now focusing on the reversibility of freshwater acidification. Streamwater and soilwater data from the Birkenes catchment in southern Norway were considered in an attempt to estimate the minimum reductions of sulfur deposition required to reintroduce brown trout to the stream. The approach taken was to derive a lower bound for the required reduction based on a suitable definition of the acid-neutralization capacity (ANC). The results demonstrate that, for present soil conditions and atmospheric base cation inputs, a decrease of sulfate deposition of more than 85%, from 1985-1987 levels, is needed to allow successful restocking of brown trout. Since this is a minimum estimate, it is possible to envisage several mechanisms by which streamwater acidification would not be sufficiently reversible for fish survival even at 100% reduction in sulfur deposition. Rainfall and throughfall inputs of all major cations and anions, via open-field bulk precipitation and canopy throughfall, are compared with streamwater outputs in two forested catchments at higher altitudes of the Black Forest. The sites differ considerably in terms of bedrock geology, soil type, soilwater characteristics, topography, and forest management history. Chemical deposition at both sites is almost equal and, in contrast to other forest areas in Central Europe, of a low-to-moderate level. Dry deposition does not seem to play an important role. Distinct differences in the elemental output emerge owing to the differing site conditions. At Villingen, deposited nitrogen is almost totally retained, whereas at Schluchsee, nitrogen output and input are of the same order of magnitude. This is consistent with the different nitrogen nutrition level of the stands, microbial turnover in the soil, and former management practices (change of tree species, excessive nutrient export). Sulfur is not retained in either of the catchments. At Schluchsee, sulfur export exceeds input from canopy throughfall by a factor of 2.5. The higher output rates, both of nitrogen and sulfur at Schluchsee, are due to the much higher microbial mineralization of organic matter as shown by previous incubation tests. Differences in cation and proton export are mainly caused by a difference in drainage pattern. In contrast to the Schluchsee catchment, where vertical water pathways prevail, the streamwater solute output at Villingen is dominated by a shallow subsurface runoff. Atmospheric deposition is a contributing, but not the dominant factor in the biogeochemical cycling at these sites. Hence, a generally applicable quantitative definition of critical loads, especially for nitrogen, is illusory and the use of such numbers will be misleading. (Author's abstract)

Journal of Hydrology JHYDA7, Vol. 116, No. 1/4, p 101-124, August 1990. 8 fig, 7 tab, 36 ref.

Descriptors: *Acid rain, *Acid rain effects, *Air pollution effects, *Forest hydrology, *Forest watersheds, *France, *Geochemistry, *Path of pollutants, *Rainfall-runoff relationships, *Vosges Mountains, *Water chemistry, Acidification, Ion transport, Nitrogen, Precipitation, Springs, Spruce trees, Streams, Sulfur, Throughfall, Weathering.

The characteristics of surface and soil waters draining an old declining spruce stand, and their chemical behavior under acid input influence within a small catchment are described using open field precipitation, throughfalls, soil solutions, and spring and streamwater data. Precipitation is characterized by a rather low pH, resulting from a moderate global pollution climate. However, pollution peaks associated with easterly winds cause, during winter and spring, a strong increase of pollutant concentrations in open field precipitation and throughfall waters. Inputs of protons, sulfur and nitrogen, which originate mainly from dry and occult deposition, are approximately 1.8, 31, and 17 kg/hectare/year, respectively. Such inputs strongly influence the inorganic mass transfer within the ecosystem. This influence results from the low base content and coarse texture of the soils. These inputs have led to an acidification of soil solutions, an increase of their aluminum content and a decrease of exchangeable base cations, particularly for calcium; this process might be one of the fundamental causes of the deficiencies which characterize the forest decline phenomenon. In the regolith, the acid inputs strongly enhance silicate mineral weathering. However, stream waters and spring waters are not yet acidified owing to the neutralization of acid inputs by weathering in the regolith. Nevertheless, streamwater chemistry is dominated by strong acid anions which are not characteristics of waters draining bedrock in pristine areas. (Korn-PTT)

Longitudinal variations of concentration-discharge relationships and chemical fluxes were evaluated in two headwater streams at the Hubbard Brook Experimental Forest, New Hampshire. At high elevations changes in subsurface flow paths explained variations in H(+), inorganic Al and Si concentrations, whereas variations of dissolved organic carbon concentration were inconsistent with this mechanism. Flow responses of middle and low elevation subcatchments were influenced by variable contributions of hydrologic source areas and the elevational concentration gradient which exists in these catchments, but in most cases were not consistent with responses predicted by changes in flow paths. Spatial patterns of chemical fluxes indicate that, in general, catchment neutralization processes increased in effectiveness in the downslope direction. However, this pattern can be interrupted by secondary tributaries, both ephemeral and persistent, which originate in variable source areas that contribute acidic surface runoff during high flow conditions. Current models of catchment acidification need to incorporate spatial variations of biogeochemical processes and flow responses to improve predictions of short-term variations in surface water chemistry. A detailed investigation of the hydrochemical alteration of input water by vegetation and soils was undertaken in an upland catchment in the Cairngorm Mountain region of Scotland. The composition of the catchment outflow water reflects the hydrological routing of water through different soil horizons and the importance of long residence time water. There is uptake of nitrogen and neutralization of incoming anthropogenic acidity by the vegetation, and sulfate adsorption in the mineral soils. Streamwater quality is dominated by the contribution of long residence time water, especially during base flow. Sulfate retention and cation release are the major neutralization mechanisms buffering outflow chemistry at this site. (Author's abstract)

An attempt to identify chemical controls in a transitional catchment in the Cairngorm region of Scotland was made using data from two distinct sampling regimes. Annual mean data from spot samples provided general information on alkalinity sources and acidification status, and flow/ion relationships suggested a three-phase chemical response within the flow profile. Alkalinity and organics appeared to show the greatest response to flow and sulfate the smallest. Information collected from time series sampling showed significant dif-

ferences in the chemical response on the rising limb of the hydrograph compared with that on the falling limb, particularly for pH and alkalinity. In the first, low flow, response phase, the chemical changes are attributed to a simple dilution process with little or no influence form surface soil horizons. During the second and more complex intermediate flow phase, the chemical response is compatible with wetting and mixing processes in the soil horizons resulting in a more variable relationship between flow and pH/alkalinity. The delayed return of alkalinity, base cations and organics, during flow recession, to pre-event levels, indicates a reservoir of acid/organic-rich water which, until depleted, contributes a major fraction of the output water. In the third, high-flow phase, a state of chemical equilibrium appears with little or no change in ion concentrations for large changes in flow. This insensitivity reflects a relatively saturated system with establishment of major hydrological pathways which produce water of a similar chemistry. (Author's abstract)

The relationship between concentrations of aluminum and hydrogen ions in surface waters was investigated on the basis of various studies, including a regional survey of more than a thousand Norwegian lakes. It was concluded that equilibrium with a single aluminum hydroxide phase cannot account for observed aluminum concentrations and that water pathways play an important role in determining the concentrations in lake and stream water. Three interactive aspects of these factors were identified: (1) hydrological phenomena which control the proportions of waters entering the lake or stream from the upper soil zone (often highly acidic), from the lower soil zone (less acidic and higher in inorganic aluminum content), and from deeper zones such as groundwater areas (even less acidic waters that are low in inorganic aluminum); (2) individual chemical signatures--differing from site to site in response to mineralogical, geomorphological, and vegetational factors--of these soil water and groundwater components; (3) non-equilibrium kinetic processes which control aluminum mobilization and precipitation. Whatever their relative influence, it is clear that any attempt to model regional water acidification must take these factors into account. One of the major processes studied in acidification research which is still not accounted for, and is still little understood, is the mechanism which mobilizes and precipitates aluminum in both soil and streams. (Korn-PTT)

In present acidification models, soilwater characteristics, though modelled, are seldom checked against field observations. Given that such data are now collected as part of many catchment studies, a technique is developed whereby stream water can be predicted as a mixture of the observed soilwater classes or end-members. Provided that a sufficient set of end-members has been identified, a least-squares technique can be used to estimate the contribution to the stream from each end-member, whenever streamwater samples have been taken. For two catchments, Birkenes in southern Norway and Plynlimon in Mid-Wales, the analysis indicates that the soilwater end-members observed to date are insufficient to explain streamwater chemistry. However, properties of the missing soil waters have been identified, thus facilitating future field work. When an adequate set of soilwater end-members have been established, long-term predictions of changes in streamwater chemistry reduce to the problem of predicting the fate of each end-member. Thus, a separate hydrological submodel is not needed, since the mixing patterns are derived from the end-member analysis. (See also W91-02754) (Author's abstract)

Streamwater chemistry at Panola Mountain research catchment, Georgia, is explained as a mixture of representative soilwater solutions that are considered to be temporally invariant to a first approximation. The selection of three end-members from all sampled soil waters is evaluated by comparing the observed and predicted streamwater concentrations of six solutes (alkalinity, sulfate, sodium, magnesium, calcium, and dissolved silica), which are assumed to mix conservatively, and by assessing the consistence of the implied hydrograph separation with the hydrological mechanisms that are believed to be operating in this catchment. The percentage of variation in the streamwater solute concentrations explained by the end-member mixing analysis (EMMA) ranges from 82 to >97%, and the hydrograph separation is, intuitively, physically reasonable. If the correct end-members have been identified, the streamwater chemical response to different levels of acidic deposition can be predicted by examining the change in each end-member under different loads; no hydrological model is required. If a traditional hydrochemical model, which is driven by rainfall quantity and quality, is desired, this analysis provides an indication of the model structure that would be necessary to reproduce both streamwater and soilwater chemistry. A hybrid deterministic-statistical approach is proposed for modeling the extremes of water quality in catchments subjected to long-term acidification. In the area of acidification modeling, long-term models such as MAGIC (Model of Acidification of Groundwater In Catchments) have been developed to simulate long-term trends and have been applied to a wide range of catchments. The approach used in this study is based on process models describing the long-term variations in mean chemistry. Superimposed on these mean projections are distributions providing information on the extremes of water quality which are fitted to catchment data using maximum likelihood techniques. The approach is general and can be applied to the prediction of other water quality variables where samples can be regarded as belonging to a parametric probability distribution. A simple implementation of the approach using chemical data and a calibrated deterministic model for the Allt a'Mharcaidh catchment is used as an illustrative method. Data from the catchment was analyzed and a preliminary form for the distribution was chosen. The mean values produced by the MAGIC model were combined with this knowledge of the distribution and estimates of the extremes were derived. The approach is general and can be applied to the prediction of other water quality variables where samples can be regarded as belonging to a parametric probability distribution. (Korn-PTT)

A regional assessment of streamwater quality in Wales is presented which reconstructs the historical trend for acidification and predicts the effect of several pollutant deposition reduction policies, using the Model of Acidification of Groundwater in Catchments (MAGIC). The regional methodology used is a two-stage coupling of Monte Carlo simulations with a calibration procedure designed to produce a coarse fit to the joint distribution of the key streamwater quality variables. The regional model is based on data from the Welsh Water Authority Survey of 1983-1984 during which streams and lakes were sampled weekly for one year. The modeling results reveal a significant decline of water quality across the region since industrialization. The model indicates that 40% of the streams and lakes within the region have suf-

fered a decline of mean annual pH of >0.5 pH units. Predictions indicate that a 30% reduction of deposition would maintain present-day stream quality levels. Reductions of the order of 60% are required to ensure a significant recovery at most sites across the region. (Author's abstract)

Descriptors: *Bacterial physiology, *Clays, *Heavy metals, *Path of pollutants, *Soil chemistry, Biochemistry, Chemical analysis, Chromium, Copper, Fate of pollutants, Geochemistry, Industrialization, Leaching, Organic matter, Silver, Toxicity, Urbanization.

Rapid industrialization and urbanization have caused elevated levels of toxic heavy metals to enter the biosphere. Significant quantities of silver, copper, and chromium were bound to isolated Bacillus subtilis 168 walls, Escherichia coli K-12 envelopes, kaolinite and smectite clays, and the corresponding organic material-clay aggregates (1:1, wt/wt). These sorbed metals were leached with nitric acid, calcium nitrate, EDTA, fulvic acid, and lysozyme at several concentrations over 48 h at room temperature. The remobilization of the sorbed metals depended on the physical properties of the organic and clay surfaces and on the character and concentration of the leaching agents. In general, the remobilization of the metals was chromium < silver < copper. Chromium was very stable in the wall, clay, and composite systems; pH 3.0, 500 microM EDTA, 120-ppm (mg/L) fulvic acid, and 160-ppm calcium remobilized less than 32% of sorbed chromium. Silver (45 to 87%) and copper (up to 100%) were readily removed by these agents. Although each leaching agent was effective at mobilizing certain metals, elevated calcium or acidic pH produced the greatest overall mobility. The organic chelators were less effective. Lysozyme digestion of Bacillus walls remobilized copper from walls and copper-wall-kaolinite composites, but silver, chromium, and smectite partially inhibited enzyme activity, and the metals remained insoluble. The extent of metal remobilization was not always dependent on increasing concentrations of leaching agents. Sometimes the organic material-clay composites reacted in a manner distinctly different from that of their individual components. The particle size of the deposited metal may account for some of the stability changes; those metals that formed large, compact aggregates as seen by transmission electron microscopy were less likely to be remobilized. Remobilization of toxic heavy metals in sediments, soils, and the vadose zone is a complicated issue, with predictions based on single inorganic or organic component systems being too simplistic. PATHOGENIC MARINE VIBRIO SPECIES IN SELECTED NOVA SCOTIAN RECREATIONAL COASTAL WATERS.
Dalhousie Univ., Halifax (Nova Scotia). Faculty of Medicine.
A. Badley, B. Phillips, D. J. M. Haldane, and M. T. Dalton.
Canadian Journal of Public Health CJPEA4, Vol. 81, No. 4, p 263-267, 1990. 2 fig, 3 tab, 11 ref.

Descriptors: *Coastal waters, *Nova Scotia, *Path of pollutants, *Recreation, *Vibrio, *Water pollution effects, Coliforms, Estuaries, Fecal pollution, Marine bacteria, Mollusks, Pathogens, Public health, Water birds.

Seven heavily frequented coastal recreation sites serving metropolitan Halifax and Dartmouth were investigated to determine the numbers and species of pathogenic marine vibrios (PMV) present. Seawater, mussels and sea gull feces were cultured using quantitative methods and the effects of temperature and fecal pollution noted. Emergency rooms serving the sites under surveillance were monitored for PMV-related infections. All 11 recognized species of PMV were recovered from the seven sites. Estuarine sites yielded a greater variety of species and greater numbers of PMV than non-estuarine sites. Culture of hand washings after immersion in seawater did not demonstrate contamination of skin by PMV. No cases of PMV infection in the seven surveillance sites were demonstrated. PMV contamination of marine recreational waters does not frequently result in superficial infections. (Author's abstract)

POLYCHLORINATED BIPHENYLS PARTITIONING IN WATERS FROM RIVER, FILTRATION PLANT AND WASTEWATER PLANT: THE CASE FOR PARIS (FRANCE).
Paris-6 Univ. (France). Inst. d'Hydrologie et de Climatologie.
M. Chevreuil, L. Granier, A. Chesterikoff, and R. Letolle.
Water Research WATRAG, Vol. 24, No. 11, p 1325-1333, November 1990. 8 fig,1 tab, 25 ref.

Descriptors: *France, *Paris, *Path of pollutants, *Polychlorinated biphenyls, *Wastewater analysis, *Water analysis, *Water pollution sources, *Water treatment, Drinking water, Organic carbon, Partition coefficient, Seine River, Suspended matter, Wastewater, Water pollution.

The partitioning of PCBs between the aqueous and particulate phases was studied from January to December 1987 in the Seine river at Paris, as well as the quality of the drinking water produced in the Orly plant. The concentrations in the influent and the effluent of the wastewater plant of Acheres were also measured. Mean concentration in the Seine river at Paris was 115 ng/L in 1986 and 130 ng/L at Orly (upstream from Paris) in 1987, which corresponds to the heavily polluted class of the World Health Organization (WHO). Evolution of PCB concentration and speciation in waters were studied following the hydrological cycle, the suspended matter content, its mineralogy, and particulate organic carbon content. In contrast to accepted opinion, about three quarters of PCBs (73%) in the Seine were carried by the aqueous phase, with no notable influence of the hydrological cycle: suspended matters were insufficient (25 mg/L mean value) to adsorb the majority of the PCBs and their adsorption capacity varied inversely with their concentration. Therefore 67% of the PCBs of the source water were not retained by the treatment plant, and the mean concentration of the drinking water was 79 ng/L. However, in most samples the concentration of PCBs was below the 100 ng/L norm of the European Economic Community. In wastewaters the proportion of particulate PCBs was only 55%, probably due to their dissolution in greases and oils. The removal rate varied from 18 to 83% (mean 54%). Mean concentrations were 650 in wastewaters and 280 ng/L ate the outlet of the secondary settling basin. The annual estimated flux was 95 mg per capita. (Author's abstract)

PROBABILITY MODEL FOR ACID RAIN DATA.
Canada Centre for Inland Waters, Burlington (Ontario).
A. H. El-Shaarawi, and A. Naderi.
Water Research WATRAG, Vol. 24, No. 11, p 1335-1339, November 1990. 10 fig, 2 tab, 6 ref.

Descriptors: *Acid rain, *Acid rain effects, *Alkalinity, *Model studies, *Probability distribution, Box-Cox Power Transformation, Color, Data collections, Hydrogen ion concentration, Lognormal distribution.

A probability model to represent lake alkalinity distributions based on the Box-Cox power transformations and covering the family of lognormal distributions was developed. The adequacy of the lognormal distribution was assessed by testing the significance of a single parameter in the proposed model. It was shown that the three-parameter lognormal does not fit the majority of data sets from Eastern Canada. The pH-alkalinity relationship developed by Small and Sutton was previously used to yield a class of probability models representing the derived distributions for pH. The distributional model developed in this study allows more flexibility and extends the scope of applications to a wider class of distributions than what has been available. Furthermore, when the pH-Alk relationship does not hold for a particular data set, the data set (if possible) may be divided into groups so that those groups for which the pH-Alk relationship is adequate are identified. This was illustrated by dividing the data from Nova Scotia into two groups according to water color. The results indicate an improved agreement between the pH-Alk relationship and the observations when water color is =/< 30 Hazen units. (White-Reimer-PTT)

ACCUMULATION FROM WATER AND DEPURATION OF 110MAG BY A FRESHWATER FISH, SALMO TRUTTA L.
CEA Centre d'Etudes Nucleaires de Cadarache, Saint-Paul-les-Durance (France). Lab. de Radioecologie des Eaux Continentales.
J. Garnier, J. P. Baudin, and L. Foulquier.
Water Research WATRAG, Vol. 24, No. 11, p 1407-1414, November 1990. 2 fig, 5 tab, 42 ref.

Descriptors: *Bioaccumulation, *Fish physiology, *Nuclear reactors, *Path of pollutants, *Radioactive wastes, *Silver, *Trout, Kinetics, Liver, Radionuclides, Tissues, Tracers.

The radioactive isotope 110mAg, which contributes to total gamma radioactivity in low-level liquid wastes from some pressurized-water nuclear reactors, has been detected in fish living in the zones affected by waste discharges from such facilities. Accumulation kinetics were followed on a group of 20 brown trout maintained for 85 days in spring water contaminated with 30 Bq/ml of 110mAg. Because of a very significant radionuclide adsorption on all available surfaces, and in order to allow investigation of uptake under chronic exposure, the contaminated water was completely renewed three times a week. The development of radionuclide concentration in the trout followed slow uptake kinetics; the maximum contamination level would not be reached until about 900 days of exposure. The concentration factor, calculated from the ratio of the integrals of the curves representing the radionuclide concentration variations in the unfiltered water and in the fish, reached a maximum value of 9 (w/w). At the end of the 57-day exposure phase, the 110mAg organotropism, investigated on 10 individuals, showed a very high concentration in the liver, amounting to 70% of the total radioactivity in the fish. Immediately following the accumulation

period (57 days), the remaining specimens were placed in non-radioactive water. After 28 days, their radioactivity level and the 110mAg distribution in the tissues were the same as at the end of the uptake phase. (White-Reimer-PTT)

HYDROLOGIC HYDROCHEMICAL CHARACTERIZATION OF TEXAS FRIO FORMATION USED FOR DEEP-WELL INJECTION OF CHEMICAL WASTES.
Texas Univ., Austin. Bureau of Economic Geology.
C. W. Kreitler, M. S. Akhter, and A. C. A. Donnelly.
Environmental Geology and Water Sciences EGWSEI, Vol. 16, No. 2, p 107-120, 1990. 15 fig, 17 ref.

Descriptors: *Groundwater movement, *Groundwater pollution, *Hazardous waste disposal, *Injection wells, *Path of pollutants, *Texas, *Waste disposal wells, Artesian pressure, Biodegradation, Brines, Groundwater recharge, Injection, Microbial degradation, Oil fields, Saline-freshwater interfaces, Water chemistry.

Hydrologic hydrochemical investigations were conducted to determine the long-term fate of hazardous chemical waste disposed in the Texas Gulf Coast Tertiary Frio Formation by deep-well injection. Three hydrologic regimes exist within the Frio Formation: a shallow fresh to moderately saline water section in the upper 3000-4000 ft; an underlying 4000-5000 ft section with moderate to high salinities; and a deeper overpressured section with moderate to high salinities. The complexity of the hydrologic environment is enhanced due to extensive depressurization in the 4000-8000 ft depth interval, which presumably results from the estimated production of over 10 billion barrels of oil equivalent and associated brines from the Frio in the past 50 years. Because of the higher fluid density and general depressurization in the brine hydrostatic section, upward migration of these brines to shallow fresh groundwater should not occur. Depressured oil and gas fields, however, may become sinks for the injected chemical wastes. Water samples appear to be in approximate oxygen isotopic equilibrium with the rock matrix, suggesting that active recharge by continental waters is not occurring. In the northern Texas Gulf Coast region salt dome dissolution controls water chemistry. In the central and southern Frio Formation, brines from the deeper geopressured section may be leaking into the hydrostatic section. The lack of organic acids and the alteration of Frio oils from samples collected from depths shallower than approximately 7000 ft suggest microbial degradation of organic material. This has useful implications for degradation of injected chemical wastes and needs to be investigated further. (Author's abstract)

GAMMA EMITTERS IN HONG KONG WATER.
Hong Kong Polytechnic, Kowloon. Dept. of Applied Physics.
L. Shun-Yin, M. Chung-Keung, N. Wai-Kwok, and A. Shui-Chun.
Environmental Geology and Water Sciences EGWSEI, Vol. 16, No. 2, p 129-131, 1990. 3 tab, 1 ref.

Descriptors: *Baseline studies, *Gamma radiation, *Groundwater pollution, *Hong Kong, *Nuclear powerplants, *Path of pollutants, *Radioactive wastes, *Water pollution sources, Drinking water, Groundwater, Radioactivity effects, Reservoirs, Rivers, Seawater, Spectral analysis.

Radioactivity in water originates from natural and artificial sources. The development of a nuclear powerplant near Hong Kong necessitates that attention be given to formulating techniques to assess the possible resultant environmental radioactive contamination. Water samples collected from various sites in Hong Kong in the spring and summer of 1987, representing seawater, river water, reservoir water, drinking water, and underground water were studied through gamma-ray spectral analysis. Only gamma emitters in the U238 and Th232 series and K40 were detected. No fission product was detected with specific activity above 0.1 Bq/kg. The data could be the baseline for future monitoring of the radioactivity released from a nuclear plant being built at a 50-km distance from Hong Kong. The variation of detected specific activities may be due to geological differences and the effect of plants. (Author's abstract) (Fish-PTT)

TRANSFORMATION OF MONOAROMATIC HYDROCARBONS TO ORGANIC ACIDS IN ANOXIC GROUNDWATER ENVIRONMENT.
Geological Survey, Reston, VA.
I. M. Cozzarelli, R. P. Eganhouse, and M. J. Baedecker.
Environmental Geology and Water Sciences EGWSEI, Vol. 16, No. 2, p 135-141, 1990. 4 fig, 21 ref.

Descriptors: *Benzenes, *Biodegradation, *Biotransformation, *Fate of pollutants, *Groundwater pollution, *Hydrocarbons, *Oil spills, *Organic compounds, Anoxic conditions, Organic acids.

The transformation of benzene and a series of alkylbenzenes was studied in anoxic groundwater of a shallow glacial-outwash aquifer near Bemidji, Minnesota. Monoaromatic hydrocarbons, the most water-soluble components of crude oil, were transported downgradient of an oil spill, forming a plume of contaminated groundwater. Organic acids that were not original components of the oil were identified in the anoxic groundwater. The highest concentrations of these oxidized organic compounds were found in the anoxic plume where a decrease in concentrations of structurally related alkylbenzenes was observed. These results suggest that biological transformation of benzene and alkylbenzenes to organic acid intermediates may be an important attenuation process in anoxic environments. The transformation of a complex mixture of hydrocarbons to a series of corresponding oxidation products in an anoxic subsurface environment provides new insight into in situ anaerobic degradation processes. ESTIMATION OF THE CONTRIBUTION OF THE SULFATE ION TO RAINWATER ACIDITY.
Kanazawa Univ. (Japan). Faculty of Technology.
E. Hirai, M. Miyazaki, T. Chohji, M. Kitamura, and N. Okubo.
Environmental Technology (Letters) ETLEDB, Vol. 11, No. 8, p 757-764, 1990. 7 fig, 10 ref.

Descriptors: *Acid rain, *Instrumentation, *Meteorological data, *Sulfates, *Water pollution sources, Anions, Atomic absorption spectrophotometry, Chlorides, Hydrogen ion concentration, Ion exchange chromatography, Ion-selective electrodes, Japan, Nitrates.

A new method to estimate the contribution of sulfate to acidity in rainwater has been developed. Rainwater samples were analyzed for pH, NH4(+), SO4(-2), NO3(-), Cl(-), Ca(+2), Mg(+2), Na(+), and K(+). Analytical methods were as follows: pH was determined by an ion electrode probe; NH4(+) by an indophenol method; anion by ion chromatography; and metallic cations by atomic absorption spectrophotometry. The application of the method was demonstrated using rainwater data representing four local weather configurations collected at Kanazawa, an area of low industrial activity on the Japan Sea side of Japan. Contribution percentages of the sulfate ion, the main contributor, to acidity in rainwater of a pH between 4.0 and 4.6 were approximately 70% during non-winter weather, and about 85% during winter. Contribution ratios of nitrate and chloride ions, which are expected to account for the remaining acidity, could not be determined with the same accuracy, because the relationship of those ions with the total cation concentration is not as simple as that of the sulfate ion. Results were also compared to estimates based on the widespread method of using excess sulfate (non-seasalt-derived sulfate) for the estimation of acidity. An estimation of the contribution of these anions will soon be made available, and it is expected that their contribution ratios will also prove valuable for the analysis of acid rain phenomena. CHEMICAL CONSTITUENTS OF PRECIPITATION AND THEIR ROLE IN DETERMINING ITS ACIDITY IN BOMBAY.
Indian Inst. of Tech., Bombay. Centre for Environmental Science and Engineering.
V. K. Sharma, P. P. Joshi, and R. S. Patil.
Environmental Technology (Letters) ETLEDB, Vol. 11, No. 8, p 777-784, 1990. 1 fig, 6 tab, 13 ref.

Descriptors: *Acid rain, *Acid rain effects, *Air pollution, *Hydrogen ion concentration, *India, *Water pollution sources, Aerosols, Ammonia, Bombay, Chemical analysis, Chlorides, Nitrates, Nitric acid, Physical analysis, Seawater, Sulfates, Sulfuric acid.

Acidity of precipitation, especially for industrialized regions, has been the subject of concern and research in recent times. Many studies in western countries have reported that acid deposition is increasing and this is mainly due to H(+) ions associated with the anions SO4(--), NO3(-), and Cl(-) which are generated primarily from anthropogenic emissions. Physical and chemical analysis of precipitation in Bombay, India, was conducted at two sites. The samples were analyzed for 12 physical and chemical constituents. It was observed that HNO3, H2SO4, and HCl were responsible for lowering the pH but due to high emissions of ammonia there was a neutralizing effect. The rain was found to be mostly alkaline in nature. The considerable emission of NH3 in the atmosphere causes a reaction to form (NH4)2SO4 which has a neutralizing effect. Calculations of sea salt ratios and ionic balance of aerosols indicate the significant contribution from continental and anthropogenic sources. (Fish-PTT)

SOURCES AND SINKS OF FORMIC, ACETIC, AND PYRUVIC ACIDS OVER CENTRAL AMAZONIA. 2. WET SEASON.
National Aeronautics and Space Administration, Hampton, VA. Langley Research Center.
R. W. Talbot, M. O. Andreae, H. Berresheim, D. J. Jacob, and K. M. Beecher.
Journal of Geophysical Research (D) Atmospheres JGRDE3, Vol. 95, No. 10, p 16,799-16,811, September 10, 1990. 10 fig, 4 tab, 40 ref. NSF Grant Nos. NSF-ATM 8413153 and NSF-ATM 8858074.

Descriptors: *Acetic acid, *Acid rain, *Amazon River Basin, *Atmospheric chemistry, *Formic acid, *Pyruvic acid, *Seasonal variation, *Water chemistry, Aerosols, Chemical interactions, Fluctuations, Forests, Model studies, Tropical regions.

The gas phase concentrations of formic (HCOOH), acetic (CH3COOH), and pyruvic (CH3C(O)COOH) acids in the forestry canopy, boundary layer, and free troposphere over the central Amazon Basin during the April-May segment of the 1987 wet season have been determined. At 150-m altitude in the boundary layer the daytime average concentrations were 430 +/-225, 340 +/-155, and 25 +/-15 ppt for HCOOH, CH3COOH, and CH3C(O)COOH, respectively. These values were five-fold lower than those observed in the 1985 dry season. Concentrations measured near the canopy top were not significantly different from boundary layer values (P = 0.10), while concentrations in the lower canopy were significantly less. Concentrations in the free troposphere (5 km) were lower than in the boundary layer and averaged 170 +/-40, 210 +/-40, and 15 +/-15 ppt for HCOOH, CH3COOH, and CH3C(O)COOH, respectively. Five-fold enhancements of CH3C(O)COOH concentrations were observed in convective outflows at 5 to 6 km altitudes. Aerosol carboxylate concentrations were usually below the detection limits of 5-10 ppt.

Preliminary branch enclosure measurements indicated significant direct emission of carboxylic acids by vegetation. A one dimensional photochemical model for the canopy and the boundary level was used to examine the contributions from various sources to the carboxylic acid budgets. Model results indicate that direct emissions from vegetation can account for most of the concentrations observed in the canopy. These emissions peak during the daytime hours. Direct emissions from vegetation can account for only a small fraction of the observed carboxylic acid concentrations in the boundary layer, suggesting a large contribution from atmospheric sources. appear to be too slow to explain the observed concentrations. Other atmospheric reactions, so far unidentified, could make a major contribution to the carboxylic acid budgets. (Author's abstract)

ournal of Geophysical Research (D) Atmospheres GRDE3, Vol. 95, No. 10, p 16,813-16,824, September 20, 1990. 10 fig, 3 tab, 57 ref. NASA roposheric Chemistry Program Grant No. AG-1-588; NSF Grant Nos. ATM-8407137, TM-8413153, ATM-8858074.

escriptors: *Amazon River Basin, *Atmospheric emistry, *Path of pollutants, *Sulfur cycle, Vater pollution sources, Aerosols, Canopy, Fors, Model studies, Sulfates, Sulfides, Sulfur compunds, Tropical regions.

e fluxes and concentrations of atmospheric fur species at ground level and from aircraft er the Amazon Basin during the 1987 wet season re determined, providing a comprehensive deiption of the sulfur cycle over a remote tropical gion. The vertical profile of dimethyl sulfide MS) during the wet season was found to be very ilar to that measured during the dry season, ggesting little seasonal variation in DMS fluxes. e concentrations of hydrogen sulfide (H2S) re almost an order of magnitude higher than se of DMS, which makes H2S the most impor- t biogenic source species in the atmospheric fur cycle over the Amazon Basin. The flux of MS at the top of the tree canopy was determined ng the gradient-flux approach. The canopy was ource of DMS during the day, and a weak sink ring the night. Measurements of sulfur gas emisns from soils, using the chamber method, wed very small fluxes, consistent with the hyhesis that the forest canopy is the major source sulfur gases. The observed soil and canopy ssion fluxes are similar to those measured in perate regions. The concentrations of SO2 and ate aerosol in the wet season atmosphere were ilar to dry season values. The sulfate concentra- in rainwater, on the other hand, was lower by actor of 5 during the wet season. Due to the her precipitation rate the wet deposition flux of ate was not significantly different between the ons. The measured fluxes and concentrations of S, H2S, and SO2 were consistent with a model cribing transport and chemistry of these sulfur cies in the boundary layer. The concentration aerosol and the sulfate deposition rate could be explained by import of significant amounts marine and anthropogenic sulfate aerosol into Amazon Basin. (Author's abstract)

ACHING OF PESTICIDES FROM TREATED MBERS--A SOURCE OF POLLUTION.
McNeill.
nal of the Institution of Water and Environmental Management JIWMEZ, Vol. 4, No. 4, p 330-334, August 1990. 3 fig, 4 tab, 3 ref.

Descriptors: *Leaching, *Pesticides, *Preservatives, *Saw mills, *Water pollution sources, *Wood preservatives, Dieldrin, Industrial wastewater, Lossie River, Pentachlorophenol.

Observations at a sawmill where two major spillages of preservative had led to pollution of the River Lossie indicated that bad timber treatment practices, together with minor spillages when preservative was delivered to the premises, were contributing to the overall unsatisfactory state of the watercourse. Also, soil sampling at the saw mill, and laboratory trials, revealed that the storage of freshly treated timbers can be a significant source of pollution. In order to prevent contamination of water from these sources, recommendations were issued to the sawmill, and the company relocated the timber treatment plant on a specially prepared self contained site to avoid pollution should further spillages occur. Remedial recommendations encompassed: (1) strict adherence to the preservative manufactures guidelines; (2) relocation of treatment area to a confined site; and (3) preventing future spillages. RECENT INVESTIGATION OF TOTAL CARBONATE IN THE BALTIC SEA: CHANGES FROM THE PAST AS A RESULT OF ACID RAIN.
Goeteborg Univ./Chalmers Univ. of Technology (Sweden). Dept. of Analytical and Marine Chemistry.
M. Ohlson, and L. Anderson.
Marine Chemistry MRCHBD, Vol. 30, No. 1/3, p 259-267, 1990. 3 fig, 1 tab, 12 ref.

Descriptors: *Acid rain effects, *Baltic Sea, *Carbonates, *Gulf of Bothnia, *Path of pollutants, Alkalinity, Calcium, Chemical analysis, Mixing, Salinity.

In a plot of the concentration of either total alkalinity or calcium versus salinity in the Baltic Sea, two mixing lines are evident: one for the mixing of low alkalinity river water, from the Gulf of Bothnia, with Baltic Proper surface water, and one for the mixing of Baltic Proper surface water with Kategatt water. The intercept at salinity = 0 for the Baltic-Kategatt mixing line gives the mean river concentration, which is compared with earlier results of other workers. The earlier mean river concentrations are different for both calcium and total alkalinity, but the ratio is about the same (approximately 0.41). However, a 1986 investigation gave a significantly different ratio (0.691) as a result of both an increased calcium and a decreased total alkalinity concentration. Explanations for the differences in the mean river concentration are offered, based on reactions in the drainage basins including the decay of organic matter, precipitation of acid rain, and dissolution of carbonate minerals. FATE OF ALDICARB IN THE UNSATURATED ZONE BENEATH A CITRUS GROVE.
Florida Univ., Gainesville. Dept. of Soil Science.
A. G. Hornsby, P. S. C. Rao, and R. L. Jones.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2287-2302, October 1990. 15 fig, 2 tab, 50 ref. Union Carbide Agricultural Company contract 81065-C.

Descriptors: *Aldicarb, *Citrus crops, *Fate of pollutants, *Florida, *Path of pollutants, *Pesticides, Drainage, Leaching, Root zone, Soil chemistry, Testing procedures.

A field study was conducted in a 1.6 ha citrus grove located in central Florida to evaluate transport and transformations of the nematicide aldicarb and its two metabolites (aldicarb sulfoxide and aldicarb sulfone) in the unsaturated zone over a 218-day period during 1984. Bromide leaching was also monitored to provide a tracer of water movement in this well-drained, deep, sandy soil. Aldicarb and bromide were applied in 3-m wide treatment bands located midway between tree rows (7.62 m apart) and incorporated into the top 5 cm soil by disking. This application method resulted in extreme variability in solute concentrations across and within the treatment bands, which persisted at all depths even as the pesticide and bromide leached during the study period. Aldicarb, its metabolites (sulfoxide and sulfone), and bromide leached readily through the soil and moved past the 7.92 m depth by the last sampling date (218 days). Aldicarb dissipated rapidly (half-life <= 2 weeks), yielding aldicarb sulfoxide and aldicarb sulfone. Both of these compounds also dissipated but at a rate slower than that for aldicarb. The dissipation of total carbamate residues under field conditions was characterized by a half-life of about 69 days, which was in agreement with laboratory-derived values. On the basis of the findings of this study, it is suggested that although generic guidelines are useful for studying the environmental fate of pesticides, rigid protocols should not be specified by regulatory agencies for these types of studies. Instead, a specific protocol must be developed (based on site characteristics, agricultural practices, and the chemical of interest) which can account for both extrinsic and intrinsic variability at each particular field site. Subsurface porous materials typically exhibit a large degree of natural variability in terms of their type and spatial distribution. A three-dimensional solute transport model has been developed to study detailed contaminant movements through large heterogeneous flow systems in porous media. The model is based upon a random walk particle method to treat multidimensional advection and dispersion processes in saturated or unsaturated media in a computationally efficient manner. The transport simulations are used to examine the large time and spatial effects of the variable flow field on developing solute plumes, and, in particular, to investigate the nature of the large-scale dispersive behavior. Numerical transport experiments were conducted using single realizations of random hydraulic conductivity fields with three different degrees of heterogeneity. Experiments with different source locations were used to investigate preasymptotic and nonergodic effects that would appear as differences in plume evolution among the experiments. Spatial moments of the particle distributions in statistically isotropic saturated media compare favorably with stochastic theory predictions in terms of longitudinal advection and mixing, but differ markedly from predictions of transverse mixing. The simulations also demonstrate that significant nonergodic effects occur, as reflected in strong differences in the second moment evolution curves among the individual experiments and as predicted from the ensemble stochastic theory. The solution to the finite element matrix differential equations resulting from the discretization of the contaminant transport equation is normally carried out by a finite difference approximation to the time derivative. The total computational effort in simulating a contaminant plume is then directly related to the number of unknowns and the number of time steps required to obtain accurate and stable solutions. An alternative method is the Arnoldi algorithm which uses orthogonal matrix transformations to reduce the finite element equations to a much smaller upper Hessenberg system of first-order differential equations. This new system can be solved by a standard Crank-Nicolson algorithm with very little computational effort. A matrix-vector multiplication is then used to obtain the original solution at desired time steps. The algorithm is used to simulate accurately the contaminant plumes for a strip source areal aquifer, a cross-sectional problem, and the Borden landfill in Ontario, Canada. The Arnoldi algorithm shows an impressive 613% increase in speed over the conventional Crank-Nicolson scheme for the Borden landfill. The method affords an efficient means of solving large problems, particularly when time durations are long. (Author's abstract)

The concentrations of 19 trace elements were determined by plasma emission spectrometry in organic fractions (organic solvent extractables, soluble humics, protokerogen and kerogen concentrates) separated from various recent and ancient sediments (Mangrove sediments, algal mats, oil shales, phosphorites) as well as sediments polluted by industrial metal emissions (Rhine River, Port Pirie smelter effluent). Often the organic constituents were found to be enriched in trace elements (especially B, V, Mn, Co, Ni, Cu, Zn, As, Mo, Ag, Cd, Sb, Hg, and Pb) up to more than three orders of magnitude compared to the bulk sediments, indicating the importance of organic substances with respect to transport and fixation trace elements with sediments. The formation of metal-organic associations was found to reflect the environment of deposition (marine to terrestrial) as well as diagenetic transformations (recent to ancient). Against an unpolluted natural background, increasing metal pollution led to increasing metal uptake by organic substances (especially for B, Cr, Fe, Co, Cu, Zn, As, Cd, and Pb). Harbor sediments in Dalhousie and Belledune, New Brunswick, Canada, are known to be contaminated with copper, zinc, lead, and cadmium. Relatively high concentrations of these metals in the resident organisms were reported from previous surveys. Experiments were conducted in the laboratory to study partitioning and bioavailability of heavy metals present in the contaminated sediments. A procedure to extract metals sequentially from sediments was used to determine their distribution in various geochemical fractions. A companion experiment was also set up to determine the bioavailability of trace metals from these sediments. Experimental data indicated that the metals associated with hydrous oxides of iron and manganese and the residual fraction carried the major burden of heavy metals in the sediment. Appreciable uptake of metals was observed to occur only from the Belledune sediment. Biota accumulated lead and cadmium to the greatest extent, with strontium, cobalt, and zinc taken up to a lesser degree as compared with control animals in uncontaminated sediments. Concern is directed to heavy metals associated with hydrous oxides of iron and manganese because changing environmental conditions can transfer these elements from the sediments into the aqueous phase. MONITORING AND ASSESSMENT OF MERCURY POLLUTION IN THE VICINITY OF A CHLORALKALI PLANT: I. DISTRIBUTION, AVAILABILITY AND GENOTOXICITY OF SEDIMENT MERCURY IN THE RUSHIKULYA ESTUARY, INDIA.
Berhampur Univ. (India). Dept. of Botany.
K. K. Panda, M. Lenka, and B. B. Panda.
Science of the Total Environment STENDL, Vol. 96, No. 3, p 281-296, August 1990. 5 fig, 5 tab, 26 ref.

Descriptors: *Bioassay, *Bioavailability, *Estuarine sediments, *Genotoxicity, *India, *Industrial wastewater, *Mercury, *Path of pollutants, *Water pollution effects, Bioaccumulation, Biological magnification, Hydrogen ion concentration, Roots, Sediment contamination.

Industrial effluent discharged into the Rushikulya India, estuary from a chloralkali plant has been identified as the source of mercury which has polluted the estuary for the past two decades. Sediment samples taken from eight sites representing the effluent channel, effluent discharge point and the course of the estuary, were analyzed for total mercury. The leachability of mercury from sediments was studied as a function of pH. Chemical extraction was used to assess bioavailability of mercury from the sediments. Further, sediment samples were bioassayed by the Allium micronucleus (MNC) assay. The endpoints measured were root length, root mercury (bioconcentrated mercury) and frequency of root meristematic cells with MNC. The mercury concentrations in sediment samples ranged from 1.6 to 192 mg/kg. The results indicated that pH was an important factor regulating the availability of mercury; the lower the pH the higher the availability of mercury. Of the different chemical extractants used, 0.05 M CaCl2 extractable mercury showed the highest correlation with the bioconcentrated mercury, emphasising the fact that 0.05 M CaCl2 was the best predictor of bioavailable mercury form the sediment. Similarly, the frequency of root meristematic cells with MNC was highly correlated not only with bioconcentrated mercury, but also with bioavailable mercury, as evidenced by 0.05 M CaCl2 extractable mercury. The Allium MNC assay can assess mercury pollution and takes into account the bioavailability of the metal. The overall assessment indicated that, although localized, the sediment of the estuary is contaminated with high concentrations of mercury with respect to both bioavailability and toxicity. Descriptors: *Aquifers, *Geologic fractures, *Glacial drift, *Groundwater movement, *Groundwater pollution, *Groundwater quality, *Landfills, *Mathematical models, *Model studies, *Path of pollutants, Computer models, Diffusion coefficient, Dispersivity, Effective porosity.

The potential impact on groundwater quality of contaminant migration from a landfill site, through fractured till, and into an underlying aquifer was studied. A simple, semi-analytic technique for modeling contaminant transport through the fractured till was developed, including consideration of diffusion of contaminants from the fractures into the till matrix, sorption, and radioactive decay. The model also considered the finite mass of contaminant and dilution due the flow of groundwater in the aquifer. The model can be easily implemented on a microcomputer. The model allowed examination of variations in fracture spacing, fracture opening size, thickness of the fractured zone, diffusion coefficient, dispersivity, effective porosity of the matrix, radioactive decay, Darcy velocity, thickness of the aquifer, distribution coefficient, and mass of the contaminant. A limited parametric study was made to illustrate the application of the theory, practical implications, and inter alia, examined the effects of uncertainty in fracture spacing, the thickness of the fractured till, and the effective porosity of the till matrix. lt oysters (Crassostrea gigas) were exposed to ronmental concentrations of tributyltin fluo- (2, 13.1 and 64.8 ng/L), for a period of 1 th, which included both an exposure and de-tion phase. The results showed that the diges-gland is the primary target organ. Recoverable ifications were observed at the lowest concentration. Limited necrosis was observed at the highest concentration and a longer exposure could have led to extensive and irreversible tissue lesions. Shell malformations (chambering) were observed during the depuration phase. Suggested safe tributyltin levels in mariculture waters should be < 2 ng/L. (King-PTT)

About 60 papers and reports dealing with heavy metal contents in different eel species are reviewed in order to document various patterns of uptake, elimination and accumulation of the metals and to underline their detrimental effects such as lethality and histopathology. Two main toxicological topics are considered: observation on contaminant levels in eels taken from the wild (mainly from contaminated waters), and experimental studies under laboratory conditions. Eels are found to acquire heavy metals directly from the water, from the sediments or from their food. (Author's abstract)

EFFECTS OF CALCIUM AND PH ON THE REPRODUCTIVE SUCCESS OF AMNICOLA LIMOSA (GASTROPODA).
Guelph Univ. (Ontario). School of Engineering.
M. A. Shaw, and G. L. Mackie.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 9, p 1694-1699, September 1990. 3 fig, 4 tab, 24 ref.

Descriptors: *Acid rain effects, *Acidic water, *Calcium, *Gastropods, *Hydrogen ion concentration, *Lake acidification, *Mollusks, *Reproduction, *Water chemistry, *Water pollution effects, Buffer capacity, Embryonic growth stage, Invertebrates, Laboratory methods, Limiting nutrients.

Field and laboratory experiments were designed to examine the relationship between water chemistry (especially pH and calcium) and the reproductive success of Amnicola limosa. Fecundity (number eggs/female) was positively correlated with lake buffering capacity ($P = 0.002$) in naturally occurring populations. Ther was a 66% reduction in fecundity in lakes over a pH range of 7.5 to 5.8. However, fecundity was higher than expected in a highly-coloured, low-pH lake. The number of juveniles produced per egg was not related to any water chemistry variable (multiple R-squared = 0.186). A laboratory experiment demonstrated that pH, and not calcium, was limiting embryonic development. All embryos held at pH 4.5 failed to hatch. Eggs held at pH 5.5 experienced reduced hatching success ($P = 0.013$) and delayed development ($P<0.001$) compared with those held at pH 6.5. Length of newly hatched snails did not differ significantly between treatments ($P = 0.891$). The critical calcium concentration required for embryonic development in laboratory incubation lay between 0.14 and 1.11 mg/L. This is well below the calcium concentration of acidifying lakes in south-central Ontario. (Author's abstract)

PROTECTIVE ACTION OF IONS AGAINST CADMIUM TOXICITY TO YOUNG BUFO ARENARUM TADPOLES.
Universidad Nacional de Lujan (Argentina). Lab. of Ecophysiology.
C. V. Muino, L. Ferrari, and A. Salibian.
Bulletin of Environmental Contamination and Toxicology BECTA6, Vol. 45, No. 3, p 313-319, September 1990. 1 fig, 2 tab, 21 ref. Comision de Investigaciones Cientificas Grant 7812/86.

Descriptors: *Acute toxicity, *Amphibians, *Cadmium, *Toads, *Toxicology, *Water pollution effects, Aquatic animals, Heavy metals, Inorganic ions, Ionic strength, Lethal limit.

The impact of Cd(II) on the response of tadpoles (Bufo arenarum) to solutions of varying ionic strength was investigated. At 0.5 and 1.0 mg/L of Cd(II) in ionic solutions, mortality was less than 10%; above these concentrations, toxicity showed an abrupt rise. The 96 h LC50 for tadpoles exposed to Cd(II) was 2.08 mg/L. In ion-free or non-ionic solutions, 1.0 mg/L Cd(II) caused 100% mortality within a few hours. The presence of 1.0 mg/L Cd(II) in solutions of varying ionic strength was not associated with changes in the water balance of the animals. The data indicate that inorganic ions have a protective action on the toxic effects of Cd(II). The cadmium toxicity may be interpreted as a secondary consequence of the known inhibitory effect on epithelial ATPases. (MacKeen-PTT)

SUBLETHAL EFFECTS OF 2,2-DICHLOROPROPIONIC ACID (DALAPON) ON FOSSARIA CUBENSIS, INTERMEDIATE HOST OF THE LIVER FLUKE, FASCIOLA HEPATICA.
Southern Univ., Baton Rouge, LA. Dept. of Biological Sciences.
F. A. Christian, and J. A. Thompson.
Bulletin of Environmental Contamination and Toxicology BECTA6, Vol. 45, No. 3, p 343-349, September 1990. 2 fig, 2 tab, 8 ref. NIH Grant RR 08025.

Descriptors: *Animal parasites, *Dalapon, *Herbicides, *Snails, *Toxicology, *Water pollution effects, Chronic toxicity, Dose-response relationships, Experimental data, Hatching, Liver flukes, Sublethal effects.

The chronic effects of the herbicide 2,2-dichloropropionic acid (dalapon) on the hatching success of Fossaria cubensis snails after several generations of exposure at sublethal levels were investigated. Snails were reared in dalapon at 0, 0.1, 1.0, or 10.0 mg/L for three successive generations with renewal of the dalapon solutions every 4 d. In the first generation there was 100% hatching of snails in the control by the 14th day while only 5.55%, 8.47% and 66.6% hatched in the 0.1, 1.0 and 10.0 mg/L dalapon groups, respectively. There was also a significant delay in hatching of the young snails in the dalapon-treated groups. In the 3rd generation, embryo development and hatching had improved in 0.1, 1.0 and 10.0 mg/L dalapon to 29%, 38.2% and 74.7%, respectively, by the 14th day and 100% in all groups by the 20th day. The results indicate that chronic exposure to sublethal concentrations of dalapon may decrease the time required for F. cubensis embryo development and hatching, possibly resulting in more snails available for the propagation of the liver fluke, Fasciola hepatica, which in turn could increase the incidence of liver fluke infections. (MacKeen-PTT)

OXYGEN UPTAKE OF PSEUDOSUCCINEA COLUMELLA AND FOSSARIA CUBENSIS TREATED WITH SUBLETHAL CONCENTRATIONS OF CUTRINE-PLUS, AN ALGICIDE.
Southern Univ., Baton Rouge, LA. Dept. of Biological Sciences.
F. A. Christian, and T. M. Tesfamichael.
Bulletin of Environmental Contamination and Toxicology BECTA6, Vol. 45, No. 3, p 336-342, September 1990. 1 fig, 2 tab, 13 ref. NIH Grant RR 08025.

Descriptors: *Algicides, *Oxygen uptake, *Snails, *Sublethal effects, *Toxicology, *Water pollution effects, Aquatic animals, Chelating agents, Dose-response relationships, Experimental data, Oxygen requirements.

The influence of sublethal concentrations of CUTRINE-PLUS, a copper-chelating algicide, on the oxygen uptake of uninfected (free from trematode larvae) Pseudosuccinea columella and Fossaria cubensis was investigated. Snails were treated with CUTRINE-PLUS for 3 h and oxygen consumption measurements taken every 15 min during the test period. The average oxygen consumption of P. columella control snails was 168 O(2) microl/h/g wet weight including the shell, whereas snails treated with 0.3, 0.6, 0.9, and 1.5 ppm CUTRINE-PLUS consumed an average of 127, 106, 101, and 77 O(2) microl/h/g wet weight, respectively. F. cubensis snails treated with 0, 0.3, 0.6, 0.9, and 1.5 ppm CUTRINE-PLUS consumed an average of 178, 126, 123, 122, and 97 O(2) microl/h/g wet weight, respectively. The data indicate that F. cubensis snails were less affected by CUTRINE-PLUS exposure than were P. columella. Possible explanations for the observed effects of CUTRINE-PLUS treatment included inhibition of DNA synthesis, decreased hemolymph oxygen carrying capacity, and inhibition of ATPase activity. (MacKeen-PTT)

Descriptors: *Aquatic animals, *Enzymes, *Insecticides, *Methyl parathion, *Organophosphorus pesticides, *Shrimp, *Toxicology, *Water pollution effects, Animal metabolism, Dose-response relationships, Enzyme activity, Experimental data, Sublethal effects.

The effects of exposure to methylparathion on the activities of acetylcholinesterase (AChE), acid and alkaline phosphatases (ACPase and ALPase), and on carbohydrate metabolism were studied in the penaeid prawn, Metapenaeus monoceros. Specimens were treated with 40 microg/L of methylparathion (one-third of 48 h LC50) for up to 5 days. The AChE activity of thoracic ganglionic mass was significantly inhibited in prawns exposed to methylparathion for 2, 3, 4 or 5 days. The ACPase activity of hepatopancreas was enhanced by exposure to the sublethal concentration of methylparathion, whereas ALPase activity of this organ was inhibited. A significant decrease of hepatic glycogen content was observed after treatment. The hemolymph glucose level was increased up to 4 days of exposure, leading to hyperglycemia. After 5 days of exposure hemolymph glucose was decreased significantly. The inhibition of AChE activity and accumulation of ACh at the synaptic junctions caused by methylparathion exposure may lead to the observed behavioral changes such as hyperexcitability, movement restriction, and loss of coordination and equilibrium, and ultimately, to the death of the organism. LAKE ACIDIFICATION AND FISHERIES PROJECT: BROOK TROUT (SALVELINUS FONTINALIS) EARLY LIFE STAGES.
Wyoming Univ., Laramie. Fish Physiology and Toxicology Lab.
H. L. Bergman, and J. S. Mattice.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 8, p 1578-1579, August 1990. 17 ref. Electric Power Research Institute Contract RP-2346.

Descriptors: *Acid rain effects, *Brook trout, *Fish, *Fish populations, *Lake acidification, *Lake fisheries, *Trout, *Water pollution effects, Acid lakes, Acidic water, Aluminum, Bioassay, Calcium, Embryonic growth stage, Fish eggs, Fish growth, Fish physiology, Juvenile growth stage, Larval growth stage, Toxicity, Water chemistry.

A brief review of a series of seven papers from the Lake Acidification and Fisheries (LAF) project of the Electric Power Research Institute is presented. The overall goal of the LAF Project is to determine cause-effect relationships between surface water acidification and fish population responses by integrating bioassay data from the laboratory and water quality and fish population data from the field into a predictive modeling framework. In the set of seven papers, LAF investigators report the results from a series of experiments with brook trout eggs, fry, and juveniles exposed for as long as 91 d to as many as 84 different combinations of pH (4.0-6.5), aluminum (0-1.00 mg/L), and calcium (0.5-8.0 mg/L) representative of acidic and acid-sensitive surface waters. Mortality and growth effects of acid/aluminum exposure were shown to depend on life stage. Whole body ion concentrations were found to be most affected by water calcium concentration during the full 91-d early life exposure, while pH was the dominant influence on whole body electrolytes during the 21-d yolk sac and swim-up fry exposures. The three final papers explore the effects of pulsed acid/aluminum exposure, aluminum complexation, and the relative sensitivity of different brook trout strains to combinations of acid, aluminum and low calcium concentrations. (See W91-02103 thru W91-02109) (MacKeen-PTT)

Freshly fertilized eggs, eyed eggs, yolk-sac fry, and swim-up fry of brook trout (Salvelinus fontinalis) were exposed to a matrix of 84 combinations of pH (4.0-6.5), aluminum (0-1.00 mg/L), and calcium (0.5-8.0 mg/L) in 21-91-d experiments. The response to pH, aluminum, and calcium was dependent on life stage. Sensitivity to acid toxicity generally decreased with age (freshly fertilized eggs> eyed eggs>yolk-sac fry=swim-up fry). Survival or hatching of freshly fertilized eggs and eyed eggs decreased at pH 5.2 and below, whereas survival of yolk-sac and swim-up fry was reduced at pH 4.4-4.0. Sensitivity to aluminum toxicity generally increased with age (freshly fertilized eggs=eyed eggs<yolk-sac fry<swim-up fry). At low pH, survival of freshly fertilized and eyed eggs increased with exposure to increasing aluminum concentrations. In contrast, elevated aluminum (greater than or equal to 0.333 mg/L) was often toxic to fry. Increasing calcium was beneficial to all life stages, although the magnitude of this benefit depended on life stage and on the specific pH and aluminum concentration. Survival after previous exposure to toxic combinations of pH, aluminum, and calcium generally improved during a post-exposure recovery period at pH 6.5. However, increased mortality in many exposure combinations did not begin until this recovery period. (See W91-02102 and W91-02104 thru W91-02109) (Author's abstract)

Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 8, p 1593-1603, August 1990. 10 fig, 35 ref. Electric Power Research Institute Contract RP-2346-01.

Descriptors: *Acid rain effects, *Acidic water, *Aluminum, *Analytical methods, *Brook trout, *Calcium, *Electrolytes, *Fish, *Fish populations, *Population exposure, *Trout, *Water pollution effects, Bioassay, Fish eggs, Fish physiology, Hydrogen ion concentration, Life stages, Neutron activation analysis, Tissue analysis, Water chemistry, Whole body ion concentrations.

Water Ca, rather than pH or Al, was the most important factor affecting whole body electrolyte levels in fry exposed from fertilization to swim-up (91 d) to 84 combinations of pH (6.5, 5.2, 4.8, 4.4, 4.0), Ca (0.5, 1, 2, 4, 8 mg/L), and Al (0, 12, 37, 111, 333, 1000 microg/L) in flowing soft water. Aluminum accumulation occurred only at water Al levels >111 microg/L; Al accumulation was inhibited both by increasing Ca and decreasing pH. Under control conditions (pH=6.5, Ca=2 mg/L, Al=0 microg/L), whole body Na, Cl, K, and Ca levels all increased greatly during development, while Mg decreased. Body Ca levels were elevated up to 3-fold, and Na, Cl, and K up to 2-fold by increasing water Ca at the same pH and Al. Low pH had a small negative influence, intermediate levels of Al (37, 111) had a slight positive influence, and higher levels of Al a negative influence on Na, Cl, K, and Ca levels. Whole body Mg showed opposite trends, reflecting delayed development under adverse conditions. At pH 6.5, the positive influence of increasing water Ca on most whole body ions showed a clear threshold between 0.5 and 1.0 mg/L. At lower pH, this threshold was shifted to between 2 and 8 mg/L, indicating that Ca levels sufficient to support healthy development at circumneutral pH may prove inadequate under acidified conditions. (See W91-02102 thru W91-02103 and W91-02105 thru W91-02109) (Author's abstract)

WHOLE BODY IONS OF BROOK TROUT (SALVELINUS FONTINALIS) ALEVINS: RESPONSES OF YOLK-SAC AND SWIM-UP STAGES TO WATER ACIDITY, CALCIUM AND ALUMINUM, AND RECOVERY EFFECTS.
McMaster Univ., Hamilton (Ontario). Dept. of Biology.
C. M. Wood, D. G. McDonald, C. G. Ingersoll, D. R. Mount, and O. E. Johannsson.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 8, p 1604-1613, August 1990. 10 fig, 3 tab, 36 ref. Electric Power Research Institute Contract RP-2346-01.

Descriptors: *Acid rain effects, *Acidic water, *Aluminum, *Brook trout, *Calcium, *Electrolytes, *Fish, *Fish populations, *Larval growth stage, *Trout, *Water pollution effects, Bioassay, Fish physiology, Hydrogen ion concentration, Life stages, Neutron activation analysis, Water chemistry, Whole body ion concentrations.

Water pH, rather than Ca or Al, was the most important factor affecting whole body ions in yolk-sac or swim-up fry exposed to a matrix of pH (6.5-4.0), Ca (0.5-8.0 mg/L), and Al (0-1000 microg/L). Fry were raised from fertilization day (day 0)

flowing soft water (pH=6.5, Ca=2 mg/L, Al=0microg/L), exposed to pH/Ca/Al on day 49 (yolk-sac, 2 d post-hatch) or day 70 (swim-up) for 21 d, and then allowed to recover a further 20 d. Yolk-sac fry were extremely resistant at pH greater than or equal to 4.4; developmental effects, as indicated by body weight and Mg, were negligible. However, whole body Na, Cl, K, and Ca were depressed by low pH, while water Ca was protective. Aluminum (37-111 microg/L) raised most ions above control values, while higher Al lowered them. Swim-up fry were more sensitive, showing pronounced developmental inhibition (lower weight, higher Mg) under adverse conditions; mortality continued during recovery. Low pH was again the dominant influence on body ions, water Ca was protective, while Al (12-111 microg/L) was only protective and not stimulatory. These effects persisted significantly; indeed responses in body Ca were larger after recovery than after the exposure itself. In the field, emergence from the redd into ambient acidic water is probably the critical stage. Water pH will be the principal determinant of whole body ions in alevins surviving this emergence, in contrast to fry exposed continuously from fertilization. EPIDERMAL RESPONSE TO PH, ALUMINUM, AND CALCIUM EXPOSURE IN BROOK TROUT (SALVELINUS FONTINALIS) FRY.
Wyoming Univ., Laramie. Fish Physiology and Toxicology Lab.
C. G. Ingersoll, D. A. Sanchez, J. S. Meyer, D. D. Gulley, and J. E. Tietge.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 8, p 1616-1622, August 1990. 1 fig, 2 tab, 58 ref. Electric Power Research Institute Contract RP-2346-01.

Descriptors: *Acid rain effects, *Acidic water, *Aluminum, *Brook trout, *Calcium, *Epidermis, *Fish, *Fish populations, *Hydrogen ion concentration, *Juvenile growth stage, *Population exposure, *Trout, *Water pollution effects, Analytical methods, Cell morphology, Fish eggs, Fish physiology, Microscopy, Mucous cells, Water chemistry.

Fed brook trout eggs were exposed to various concentrations of pH (4.3-6.3), aluminum (0-1000 microg/L), and calcium (0.5-8.0 mg/L) for 40 d through hatching until the swim-up life stage. High resolution light microscopy, image analysis, and morphological techniques were used to quantitatively determine morphological changes in the epidermis of fry surviving this exposure. Exposure to increased acidity resulted in both mucous cell hypertrophy (increase in size) and hyperplasia (increase in number); exposure to low calcium resulted in mucous cell hyperplasia. Aluminum did not significantly affect mucous cell size or number. Epidermal thickness was not consistently affected by exposure to pH, aluminum, or calcium. The changes observed in epidermal mucous cells may be a compensatory mechanism used by brook trout to counter ionoregulatory stress resulting from extended exposure to acidic conditions. (See W91-02102 thru W91-02105 and W91-02107 thru W91-02109) (Author's abstract)

RESPONSES OF BROOK TROUT (SALVELINUS FONTINALIS) FRY TO FLUCTUATING ACID, ALUMINUM, AND LOW CALCIUM EXPOSURE.
Wyoming Univ., Laramie. Fish Physiology and Toxicology Lab.
C. G. Ingersoll, D. D. Gulley, D. R. Mount, M. J. Swanson, J. E. Breck, A. M. Farag, and H. L. Bergman.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 8, p 1623-1630, August 1990. 2 fig, 2 tab, 41 ref. Electric Power Research Institute Contract RP-2346.

Descriptors: *Acid rain effects, *Acidic water, *Acidity, *Aluminum, *Brook trout, *Calcium, *Fish, *Fish populations, *Juvenile growth stage, *Population exposure, *Trout, *Water pollution effects, Acclimatization, Bioassay, Fish eggs, Fish growth, Fish physiology, Fishkill, Toxicity, Water chemistry, Water quality.

In certain instances, fish kills have been directly associated with acidic 'pulses'. Brook trout fry were exposed for 30 d to temporal combinations of two water qualities: (1) pH 5.21, 51 microg/L total aluminum, with 2.39 mg/L calcium (baseline); and (2) pH 4.59, 329 microg/L total aluminum with 1.56 mg/L calcium (pulse). Although continuous exposure to the pulse conditions caused nearly complete mortality, exposures alternating between the two conditions caused much less mortality. In fact, fish experiencing 18 d of baseline conditions before their first pulse exposure had mortality rates equal to fish never experiencing a pulse, indicating acclimation to acid/aluminum/low calcium stress. The data indicate that the pattern of fluctuating acid/aluminum/low calcium exposure is very important in determining its toxicity, and that the toxicity of acid 'pulses' in field situations may be lower than would be expected from laboratory exposures using naive fish, due to the existence of acclimation. INORGANIC MONOMERIC ALUMINUM AND PH AS PREDICTORS OF ACIDIC WATER TOXICITY TO BROOK TROUT (SALVELINUS FONTINALIS).
Wyoming Univ., Laramie. Dept. of Zoology and Physiology.
B. R. Parkhurst, H. L. Bergman, J. Fernandez, D. D. Gulley, and J. R. Hockett.
Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 8, p 1631-1640, August 1990. 3 fig, 5 tab, 37 ref.

Descriptors: *Acid rain effects, *Acidic water, *Acidity, *Aluminum, *Brook trout, *Fish, *Fish populations, *Hydrogen ion concentration, *Toxicity, *Trout, *Water pollution effects, Bioassay, Dissolved organic carbon, Fish physiology, Fishkill, Fluorides, Regression analysis, Survival, Water chemistry, Water quality, Water temperature.

Inorganic monomeric aluminum concentrations were found to be the primary determinant of survival of brook trout feeding fry exposed for 21 d to various combinations of total aluminum and pH, plus several concentrations of fluoride or dissolved organic carbon (DOC), or several temperatures. Total aluminum concentrations in the 4 x 4 x 4 experimental matrices ranged from 3-1276 ppb, pH from 4.4-6.7, fluoride from <10-328 ppb, DOC from <1-9.2 ppm, and temperatures from 5.4-12.0 C. Stepwise logistic regression was used to determine the significance of the effect of each water quality variable on survival. Inorganic monomeric aluminum accounted for 78-98% of the variation in survival. Except in the fluoride bioassay where pH was not significant, pH was the second factor in order of importance, accounting for up to 16% of the variation in survival. Fluoride or temperature accounted for 1-2% of the variation in survival, while DOC accounted for 6% of the variation in survival. (See W91-02102 thru W91-02107 and W91-02109) (Author's abstract)

Canadian Journal of Fisheries and Aquatic Sciences CJFSDX, Vol. 47, No. 8, p 1641-1648, August 1990. 4 fig, 1 tab, 50 ref. Electric Power Research Institute Contract RP-2346-01.

Descriptors: *Acid rain effects, *Acidic water, *Acidity, *Aluminum, *Brook trout, *Fish, *Fish populations, *Toxicity, *Trout, *Water pollution effects, Bioassay, Calcium, Comparison studies, Fish eggs, Fish growth, Fish physiology, Fishkill, Gills, Histology, Survival, Water chemistry.

Two strains of 1 yr-old brook trout were exposed to 14 combinations of pH, aluminum, and calcium during a 28-d experiment. Survival, weight, and gill histology of both strains were affected similarly by pH, aluminum, and calcium exposure. Survival was reduced at inorganic monomeric aluminum concentrations (IA1) of 29 microg/L at pH 5.2 and greater than or equal to 228 microg/L at pH 4.4 and 4.8. Fish weight was reduced with exposure to pH below 4.8 or aluminum concentrations greater than or equal to 34 microg/L. The gills sampled from fish exposed to low pH exhibited lifting of the outer epithelium and hypertrophy (increase in size) of chloride and epithelial cells. The response of gills sampled from fish exposed to low pH and elevated aluminum was more pronounced relative to the low pH exposure alone. In addition to the effects observed in the low pH exposed fish, the gills from fish exposed to both acid and aluminum exhibited vacuolation and degeneration of epithelial and chloride cells and the presence of dense cells. Finally, fish confined in PVC tubes designed to mimic in situ field exposure procedures were more sensitive to the toxic effects of acid and aluminum compared to free-swimming fish. Caution must be taken when extrapolating safe field levels from in situ exposures of caged fish. (See W91-02102 thru W91-02108) (Author's abstract)

P. M. Sivalingam, and R. Billet.
Toxicological and Environmental Chemistry TXECBP, Vol. 26, No. 1/4, p 1-14, 1990. 9 fig, 3 tab, 15 ref.

Descriptors: *Electron microscopy, *Mercury, *Path of pollutants, *Toxicity, *Toxicology, *Water pollution effects, Fish, Fish physiology, Liver, Tilapia, Tissue analysis.

The uptake of toxic heavy metals, including mercury, by aquatic flora and fauna appears to be a phenomenan involving the passive diffusion by direct absorption into the organism. Electron microscope studies of hepatic cellular alterations in fish exposed to a 75 ppb lethal dose of inorganic Hg (++) ions (in the form of HgCl2) utilized five specimens of tilapia ranging from 5.0 to 7.5 cm in length. The hepatic cells exposed to mercury for a week were comparatively empty while fat droplets, a few secondary lysosomes and mitochondria were present in the controls. The morphological structure of mitochondria was unaltered, but glycogen levels were depleted. Grape-like globulets resembling fatty bodies formed in the nuclei of the exposed fish; some nuclei possessed a lot of these bodies, while others only formed two or three. These droplets ranged between 0.2-0.5 micrometers in diameter, while those in the cytoplasm averaged 1.2 micrometers. Nevertheless, the nuclear and cellular membranes were normal. In vivo response of hepatic enzymes indicated an increase in alkaline, acid, and glucose-6-phosphatase activities while catalase was inhibited. However, under in vitro conditions all four hepatic enzymes were inhibited at varying rates. These observations show conclusively the depletion of bioenergy in relation to enhanced energy requirements, and indirect inhibition of oxidative phosphorylative processes in the electron transport system of mitochondria. In vertebrates and invertebrates Zn exists as complexed compounds with metallothioneins. However, its cellular level effects and metabolic fates are scantly documented. Electron microscopy is a useful technique for studying hepatic cellular alterations in fish, at a lethal dose exposure of 4.0 ppm over a week. A large number of lysosomes in hepatic cells prevailed on exposure to Zn in its sulfate form. Evidently, due to metal compound stress and cellular damage, lysosomal activity is augmented. The lysosomes harbored digestible material, presumably the aforementioned substrates. Fat droplets prevailed, while glycogen depletion was noticeable. Unlike the effects of Hg, the nuclei were normal with granular chromatin and prominent nucleoli. However, the mitochondria contained some small intramitichondrial bodies. Similar to the effects of Hg, the cell membrane remained intact. In vivo enzymatic studies indicated augmentation in catalase, acid and alkaline phosphatases, while glucose-6-phosphatase was inhibited. However, only alkaline and glucose-6-phosphatases were inhibited under in vitro conditions. It is evident that Zn enhances cellular bioenergetic requirements culminating in glycogen depletion owing to stress, concomitantly causing inhibition of oxidative phosphorylation in the electron transport system. Descriptors: *Aquatic habitats, *Chlorinated hydrocarbons, *Hazard assessment, *Pesticide toxicity, *Pesticides, *Structure-activity relationships, *Water pollution effects, Environmental fate, Model studies, Organic pesticides, Population exposure, Prediction.

Pesticides, including insecticides, herbicides, fungicides, and rodenticides, are widely used in many industrialized and developing countries. Organochlorine pesticides are still being widely used and are commonly found in surface waters. On the basis of physicochemical data, such as water solubility and vapor pressure, as well as acute toxicity tests, an ecotoxicological model for preliminary hazard assessment has been developed using data mostly collected from the literature. The Quantitative Structure Activity Relationship (QSAR) system was used to make predictions about the potential threat of chlorinated pesticides to aquatic organisms. By use of the reciprocal product for log H and LC50 a suitable ranking system was developed that allows the prediction of potential damage to aquatic organisms through pesticides. The QSAR system estimated chemical properties, environmental fate, and toxicity of organic compounds using models based upon chemical structure. The preliminary hazard assessment consists of an evaluation of potential exposure and the potential effects of that exposure. (Tappert-PTT)

SURVIVAL OF STRIPED BASS LARVAE AND YEARLINGS IN RELATION TO CONTAMINANTS AND WATER QUALITY IN THE UPPER CHESAPEAKE BAY.
Johns Hopkins Univ., Shady Side, MD. Aquatic Ecology Section.
L. W. Hall, A. E. Pinkney, R. L. Herman, and S. E. Finger.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 4, p 391-400, July 1987. 1 fig, 8 tab, 21 ref. The Johns Hopkins University/FWS Cooperative Agreement No. 14-16-0009-85-910.

Descriptors: *Bass, *Chesapeake Bay, *Estuarine environment, *Larval growth stage, *Survival, *Water pollution effects, Acute toxicity, Animal pathology, Fish pathology, Fishkill, Histology, Laboratory methods, Larvae, Toxicology.

This study was designed to: evaluate the survival of striped bass yolk-sac larvae and yearlings at three locations in their natural spawning habitat in the upper Chesapeake Bay (Chesapeake and Delaware Canal) using 'in situ' chambers; correlate larval and yearling survival with the presence of 11 water quality parameters, 10 inorganic contaminants and 21 organic contaminants; and assess histological effects on yearlings after exposure to habitat water. The cumulative percent survival ranged from 42-59.5% for striped bass larvae after 96 hr of exposure to habitat water during two experiments. Survival in control conditions during these two experiments was 77.5% and 80.5%. Data from previous studies have shown that mortality rates for wild yolk-sac larvae ranged from 7-19% per day. Daily mortality of larvae in the present study was 13-16%; therefore, suspected acutely harmful water quality or contaminant conditions affecting survival were not substantiated. All yearling striped bass survived 10 days of exposure to habitat water. Although habitat water was not acutely toxic, histological examination of surviving yearling striped bass indicated sublethal effects. Telangiectases (lamellar dilations) of the gills was reported for yearlings exposed to habitat water. This pathological change was not found in the controls. (Author's abstract)

SHORT-TERM EXPOSURE OF ZOOPLANKTON TO THE SYNTHETIC PYRETHROID, FENVALERATE, AND ITS EFFECTS ON RATES OF FILTRATION AND ASSIMILATION OF THE ALGA, CHLAMYDOMONAS REINHARDII.
Guelph Univ. (Ontario). Dept. of Environmental Biology.
K. Day, and N. K. Kaushik.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 4, p 423-432, July 1987. 3 fig, 3 ref, 41 ref.

Descriptors: *Acute toxicity, *Bioindicators, *Chlamydomonas, *Fenvalerate, *Pesticides, *Toxicology, *Water pollution effects, *Zooplankton, Bioassay, Biological studies, Daphnia, Feeding rates, Laboratory methods, Lethal limit, Waterfleas.

The feeding behavior of zooplankton is a physiological function which may be of value in the study of the toxicity of pollutants to aquatic organisms. In acute tests of toxicity, two cladocerans, Daphnia galeata mendotae and Ceriocaphnia lacustris, and the calanoid, Diaptomus oregonesis, were more sensitive to fenvalerate (FV) than Daphnia magna, the organism used in standard laboratory bioassays. The 48-hr 50% lethality concentrations (EC50s) for each species/stage in order of increasing sensitivity were adult D. magna-2.52 micrograms/L; D. magna (</=48-hr old)-0.83 micrograms/L; adult D. galeata mendotae-0.29 micrograms/L; adult C. lacustris-0.21 micrograms/L; D. galeata mendotae (</=48-hr old)-0.16 micrograms/L; and adult Diaptomus oregonensis-0.12 micrograms/L. No toxicity was observed when these organisms were exposed to a range of concentrations of the emulsifiable concentrate without FV (the EC blank). Rates of filtration of the 14-C labeled alga, Chlamydomonas reinhardii by D. galeata mendotae, C. lacustris and D. Oregonensis were decreased significantly at sublethal concentrations of FV after only 24-hr exposure. Ceriodaphnia lacustris showed the greatest sensitivity with rates of filtration significantly decreased at 0.01 micrograms FV/L. Concentrations of FV >/=0.05 micrograms/L resulted in decreased rates of filtration by D. galeata mendotae. A concentration of 0.10 micrograms FV/L caused rates of filtration to increase in D. oregonensis, whereas 0.05 and 0.5 micrograms/L resulted in a decrease in these rates. Rates of assimilation of algae by D. galeata mendotae, C. lacustris and D. oregonensis exposed to similar concentrations of fenvalerate were decreased at concentrations >= 0.05 micrograms FV/L. Changes in rates of assimilation were not as sensitive a parameter of toxicity as changes in rates of filtration. The EC blank had no significant effects on rates of filtration or assimilation for all three species. (Author's abstract)

CHANGES IN PLASMA, LIVER, AND OVARY VITELLOGENIN IN LANDLOCKED ATLANTIC SALMON FOLLOWING EXPOSURE TO SUBLETHAL CYANIDE.
Concordia Univ., Loyola Campus, Montreal (Quebec). Dept. of Biology.
S. M. Ruby, D. R. Idler, and Y. P. So.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 4, p 507-510, July 1987. 1 fig, 1 tab, 30 ref.

Descriptors: *Acute toxicity, *Cyanide, *Fish physiology, *Salmon, *Toxicology, *Water pollution effects, Immunoassay, Laboratory methods, Liver.

Hydrogen cyanide (HCN) is a toxicant that occurs frequently in terrestrial and aquatic ecosystems both naturally and from man-made sources, and affects fish physiology, particularly reproduction. Female landlocked Atlantic salmon (Salmo salar Ouananiche) were exposed to 0.005 mg/L HCN for 12 days at 7 +/-1 C during late vitellogenesis (October). Plasma vitellogenin and liver and gonad vitellogenin-like protein (VLP) levels were measured by homologous radioimmunoassay specifically developed for this species. Results indicated that plasma vitellogenin levels increased in cyanide exposed fish. VLP levels in the liver did not change relative to control fish suggesting that the increased levels of plasma vitellogenin did not result from a change in synthesis in the liver. VLP levels declined in the gonad relative to the control by day 12. Elevated plasma vitellogenin level along with decreased VLP in the gonads suggests that exposure of female salmon to sublethal HCN during late vitellogenesis inhibits the uptake of vitellogenin at the ovarial level. The recommended safe concentration for cyanide (0.005 mg/L) which offers a safe water quality objective alters pattern of plasma vitellogenin just prior to spawning. (Author's abstract)

SHORT-TERM LETHALITY AND SEDIMENT AVOIDANCE ASSAYS WITH ENDRIN-CONTAMINATED SEDIMENT AND TWO OLIGOCHAETES FROM LAKE MICHIGAN.
Michigan Univ., Ann Arbor. Great Lakes Research Div.
T. J. Keilty, D. S. White, and P. F. Landrum.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 1, p 95-10 January 1988. 2 fig, 4 tab, 35 ref. Great Lakes Environmental Research Laboratory/NOAA Cooperative Agreement NA81-RA-H-00003.

Descriptors: *Acute toxicity, *Bioassay, *Endrin, *Lake Michigan, *Lake sediments, *Oligochaete, *Path of pollutants, *Sediment contamination, *Toxicology, *Water pollution effects, Animal behavior, Benthic fauna, Fate of pollutants, Halogenated pesticides.

Toxic compounds with high partition coefficient that enter the Laurentian Great Lakes adsorb significantly to fine particles and settle to the bottom. The fate of these compounds and their interaction with the larger benthic organisms is largely unknown. Mean 96-hr 50% lethality (LC50) values and standard deviations for the oligochaetes Stylodrilus heringianus and Limnodrilus hoffmeisteri exposed to endrin-contaminated sediments w

2588+/-1974 micrograms/g dry weight sediment for 4 assays and 2725+/-955 micrograms/g for 2 assays, respectively. Mixed species testing data suggested that the toxicity to L. hoffmeisteri was reduced in the presence of S. heringianus, yet further testing is required. Ninety-six hour 50%-effective (EC50) burrowing avoidance values for both species (19 and 15.3 microgram/g for S. heringianus and 59 micrograms/g for L. hoffmeisteri) were approximately 46 and 150 times lower than their respective mean 96-hr LC50 values. Both S. heringianus and L. hoffmeisteri initially burrowed in contaminated sediment and then returned to the surface in numbers somewhat proportional to the sediment concentration and length of exposure. Future use of oligochaete behavioral responses to sublethal sediment contamination for pollution impact on benthic communities is promising. (Author's abstract)

ARTIFICIALLY INDUCED METAMORPHOSIS ACETONE IN ACRIS GRYLLUS.
Tennessee State Univ., Nashville. Dept. of Biological Sciences.
S. Pollard, and J. A. Adams.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 4, p 419-428, July 1988. 8 fig, 2 tab, 21 ref. NIH Grant No. SO6RR08092.

Descriptors: *Acetone, *Amphibians, *Bioindicators, *Frogs, *Metamorphosis, *Toxicology, *Water pollution effects, Hormones, Iodine, Laboratory methods, Larval growth stage, Thyroid gland.

The causative agents (hormones) involved in amphibian metamorphosis as well as the involved specific endocrine organs have been well established for decades. Tri-iodothyronine and thyroxin, both secretions of the larval thyroid gland, are directly responsible for metamorphosis under physiological conditions. High amounts of the element iodine (approximately 300 times the amount found in equally effective levels of thyroxin) can also induce metamorphosis in amphibians. In a search for an appropriate emulsifier to be employed in studying the effects of hydrophobic polychlorinated biphenyls (PCBs) on metamorphosis, reagent-grade acetone (a commonly-used carrier molecule for PCBs) was found to be a potent inducer of metamorphosis in Acris gryllus (a cricket frog species). The acetone was employed as a component of an artificial pond water medium. Other test conditions included exposure to thyroxin and dimethyl sulfoxide for comparison. Not only was metamorphosis enhanced in the acetone-treated animals, but the effect was concentration-dependent when acetone levels of 10 mg/L and 50 mg/L were employed. The 50 mg/L acetone-treated group showed precocious metamorphosis at a rate not significantly different from that produced by thyroxin. Dimethyl sulfoxide exposure produced no significant increase in metamorphic rate. (Author's abstract)

EFFECTS OF ATRAZINE ON FRESHWATER MICROBIAL COMMUNITIES.
Pennsylvania State Univ., University Park. School of Forest Resources.
R. Pratt, N. J. Bowers, B. R. Niederlehner, and J. Cairns.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 4, p 449-457, July 1988. 2 fig, 4 tab, 44 ref. EPA Grant R-2813-01-0 and Air Force Office of Scientific Research Grant AFOSR-85-0324.

Descriptors: *Atrazine, *Bioassay, *Bioindicators, Herbicides, *Pesticides, *Toxicity, *Toxicology, Water pollution effects, Algae, Aquatic fungi, Biomass, Calcium, Chlorophyll a, Colonization, Dissolved oxygen, Laboratory methods, Magnesium, Microbial degradation, Proteins, Protozoa, Species diversity.

A multispecies toxicity test system using naturally-derived microbial communities (comprised of bacteria, fungi, protozoa, algae and micrometozoans) on polyurethane foam substrates was used to evaluate the toxic effects of the herbicide atrazine. Both structural (e.g., protozoan species number, biomass) and functional (e.g., colonization rate, oxygen production) community responses were measured. Oxygen production and the ability of communities to sequester Mg and Ca were the most sensitive measures of toxic stress due to atrazine (maximum allowable toxicant concentrations (MATCs) = 17.9 micrograms/L). Dissolved oxygen was 33% lower, and there was 15% less Ca and Mg in communities at and above 32.0 micrograms/L atrazine compared to controls. Species richness and estimates of biomass (total protein and chlorophyll a) were less sensitive (MATCs = 193) to atrazine. At the highest atrazine concentration (337 micrograms/L), species numbers were 30% lower than controls, and protein and chlorophyll a content of communities were reduced by 38 and 91%, respectively. Low levels of atrazine (3.2-32.0 micrograms/L) resulted in a 46% increase in species numbers and a greater concentration of total protein and chlorophyll a (41 and 57%, respectively). Results compared well with other estimates of chronic toxicity for effects of atrazine on aquatic communities. Reported MATCs ranged from 70.7 to 3400 micrograms/L. The results from this test emphasize the importance of monitoring both structural and functional measures of community integrity in toxicity testing with multispecies. (Author's abstract)

RESPONSES OF ZOOPLANKTON AND CHAOBORUS TO TEMEPHOS IN A NATURAL POND AND IN THE LABORATORY.
Saint Olaf Coll., Northfield, MN. Dept. of Biology.
J. C. Helgen, N. J. Larson, and R. L. Anderson.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 4, p 459-471, July 1988. 9 fig, 4 tab, 24 ref. EPA/St. Olaf College Cooperative Agreement Cr-810016-01.

Descriptors: *Bioindicators, *Chronic toxicity, *Organophosphorus pesticides, *Pesticides, *Ponds, *Toxicology, *Water pollution effects, *Waterfleas, *Zooplankton, Acute toxicity, Bioassay, Copepods, Daphnia, In situ tests, Laboratory methods, Larval growth stage, Life cycles, Minnesota, Risk assessment, Rotifers.

A two year field study was performed on the effects of the organophosphorus insecticide temephos on zooplankton and the phantom midge larva Chaoborus americanus in natural ponds in central Minnesota. Application of temephos to a pond was followed by reduction within 24 hr in all cladocerans, in Diaptomus leptopus and in C. americanus, and increases in cyclopoid copepods, copepod nauplii and the rotifer Keratella cochlearis. Daphnia pulex that reappeared 35 days post-application were ex-ephippial. After application, reproduction of cladocerans and Diaptomus was markedly reduced compared to the previous year, an effect attributed to temephos. Daphnia population density was strongly reduced into the fall season, long after the spring applications, compared with both a reference pond's and the previous season's populations. On-site bioassays demonstrated 24-hr mortalities of Daphnia and Chaoborus that were comparable to the population decreases in the pond. Laboratory toxicity tests showed Daphnia was the most sensitive followed by Chaoborus and Diaptomus. Comparable results were seen in the pond population changes, in situ bioassays and laboratory toxicity data for Daphnia and for Chaoborus, but sensitivities in the pond were somewhat greater than in the laboratory. Risk assessment research calls for long-term field reproduction analysis to avoid a false 'recovery' report, combined with laboratory life cycle analysis and short acute exposure tests. (Author's abstract)

CALCIUM METABOLISM IN TWO POPULATIONS OF THE SNAIL HELIX ASPERSA ON A HIGH LEAD DIET.
Polytechnic of the South Bank, London (England). Dept. of Biotechnology.
A. Beeby, and L. Richmond.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 4, p 507-511, July 1988. 3 fig, 3 tab, 20 ref.

Descriptors: *Air pollution effects, *Animal metabolism, *Calcium, *Lead, *Snails, *Toxicology, Bioassay, Chemical analysis, Excretion, Heavy metals, Magnesium, Trace metals.

The uptake and loss of toxic metals by organisms may depend on their mechanisms for binding and excreting essential metals. Ca is often associated with heavy metal retention in vertebrates and invertebrates. Soft tissue concentrations of Pb, Ca and Mg were measured in two populations of the garden snail, Helix aspersa, over a 64-day dosing regime to determine if differences in Pb metabolism could be predicted by differences in Ca metabolism. Snails compared from an uncontaminated site and from a grossly polluted car park. In each case, 25 snails were given a diet with 500 micrograms/g Pb (as PbSO4), and 25 were removed to a Pb-free diet after two days on the Pb dose. The snails from the car park maintained a higher concentration of Ca in the soft tissues, and assimilated Ca faster on a high Pb diet. Concentrations of Pb and Ca can be correlated for the soft tissues of the dosed car park snails. No such relationship was found for the snails from the rural site. The rate of Ca assimilation may determine the excretion rate of intracellular granules, where Pb is bound. Population differences in Pb uptake might result from variations in Ca metabolism, which, in the car park snails, could represent an adaptation to high ambient Pb. (Author's abstract)

SELENIUM TERATOGENESIS IN NATURAL POPULATIONS OF AQUATIC BIRDS IN CENTRAL CALIFORNIA.
Patuxent Wildlife Research Center, Laurel, MD.
D. J. Hoffman, H. M. Ohlendorf, and T. W. Aldrich.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 4, p 519-525, July 1988. 8 fig, 2 tab, 28 ref.

Descriptors: *California, *Kesterson Reservoir, *Selenium, *Teratogenic effects, *Water birds, *Water pollution effects, *Waterfowl, Agricultural runoff, Eggs, Embryonic growth stage, Liver, Trace metals.

The frequency and types of malformations are described that were encountered during the spring of 1983 in a natural population of aquatic birds exposed to agricultural drainwater ponds and food items containing high concentrations of Se in central California. A total of 347 nests of aquatic birds containing 1,681 eggs was selected for study at Kesterson Reservoir located in the Kesterson National Wildlife Refuge, Merced County, California. Embryos collected during incubation or from eggs that failed to hatch were examined to determine the age at death and presence of malformations. Embryonic death was generally high; approximately 17-60% of the nests of different species contained at least one dead embryo. The incidence of malformed embryos was also high; approximately 22-65% of the nests where at least two embryos were examined contained abnormal embryos. American coots (Fulica americana) and black-necked stilts (Himantopus mexicanus) experienced the highest incidence of malformed embryos. For all species, the average percentage of eggs containing dead or live abnormal embryos was 16.1 whereas the average percentage containing live abnormal embryos was 10.7. Multiple gross malformations of the eyes, brain, and feet were often present. Brain defects included hydrocephaly and exencephaly. Eye defects included both unilateral and bilateral anophthalmia and microphthalmia. Eye and foot defects with ectrodactyly and swollen joints were the most common in coots. Beak defects also occurred frequently and most often included incomplete development of the lower beak of ducks (Anas spp.) and stilts. Wing and leg defects were most prevalent in stilts and ducks, with ectromelia and amelia most prevalent in stilts. Other malformations occurring at lower frequencies included enlarged hearts with thin ventricular

walls, liver hypoplasia, and gastroschisis. Based upon simultaneous examination of a control population of aquatic birds of the same species and published studies, the incidences of embryonic mortality and deformities were 9-30 times greater than expected. (Author's abstract)

WEATHERED CRUDE OIL EFFECTS ON CHICKS OF FORK-TAILED STORM-PETRELS (OCEANODROMA FURCATA).
Washington Univ., Seattle. Inst. for Environmental Studies.
P. D. Boersma, E. M. Davies, and W. V. Reid.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 4, p 527-531, July 1988. 3 tab, 23 ref.

Descriptors: *Chronic toxicity, *Hydrocarbons, *Oil pollution, *Prudhoe Bay, *Toxicology, *Water birds, *Water pollution effects, Marine pollution, Oil, Oil spills.

Adult Storm-Petrels had between 0.004 and 0.0008 ml of fossil fuel hydrocarbons present in their food samples when they were considered contaminated. Chicks of Fork-Tailed Storm-Petrels (Oceanodroma furcata) were fed 0.1 ml of weathered Prudhoe Bay crude oil, which should be close to the maximum dose that they might receive at a feeding. Chicks dosed orally once, twice, or weekly with 0.1 ml weathered Prudhoe Bay crude oil did not differ significantly in gross morphology, bill, tarsus, or wing growth from control chicks. Chicks dosed one time gained weight between the ages of 0-21 days at significantly slower rates. Chicks aged 22-51 days grew similarly regardless of treatment. Dosed chicks fledged on average two days later than control chicks. Ingesting small amounts of weathered oil had little effect perhaps because Storm-Petrels may be able to ingest long-chained hydrocarbons (like petroleum) with relative impunity, because these compounds are relatively nontoxic and are part of their normal diet. (Author's abstract)

ECOLOGY OF A SOUTHERN OHIO STREAM RECEIVING FLY ASH POND DISCHARGE: CHANGES FROM ACID MINE DRAINAGE CONDITIONS.
American Electric Power Service Corp., Columbus, OH. Environmental Engineering Div.
R. J. Reash, J. H. Van Hassel, and K. V. Wood.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 4, p 543-554, July 1988. 3 fig, 4 tab, 46 ref.

Descriptors: *Acid mine drainage, *Acid streams, *Ecological effects, *Ecosystems, *Fly ash, *Ohio, *Stabilization ponds, *Waste disposal, *Water pollution effects, *Water pollution treatment, Benthic environment, Benthic fauna, Electric power industry, Electric powerplants, Fish, Hydrogen ion concentration, Species diversity, Water pollution control.

Prior to 1975, Stingy Run was a third-order tributary of Kyger Creek, which empties into the Ohio River at Mile 260 (Gallia County, Ohio). Both streams drained strip mine refuse areas and physicochemical measurements indicated acidic-mine drainage conditions (e.g., low pH). A depauperate macroinvertebrate community, dominated by a few acid-tolerant taxa, was found in both streams and no fishes were collected. In 1974, Stingy Run was impounded to form a fly ash pond which contains fly ash sluiced from Ohio Power Company's General James M. Gavin coal-fired power plant. Physicochemical and biological sampling during 1975-1986 indicated marked changes in the aquatic ecology of Stingy Run between (1) preimpoundment and post-impoundment conditions; and (2) effluent pH control treatments after impoundment. Fly ash discharge eliminated acidic-mine drainage characteristics in Stingy Run and lower Kyger Creek. After impoundment, net spinning caddisflies and a few dipteran taxa dominated the Stingy Run benthic community, reflecting changes in functional niches likely due to improved habitat and greater food availability. Replacement of acid feed by CO2 injection for effluent pH control and changes in ash pond chemistry occurred concomitant with elimination of a substrate floc; increased species richness and densities of invertebrates were subsequently observed. In Stingy Run, species richness and diversity of fishes increased from 1983 to 1986, reflecting improved water quality and increased benthic production after impoundment. Many of these fishes are opportunistic feeders on drifting insects. (Author's abstract)

POPULATION-SPECIFIC TOXICITY RESPONSES BY THE FRESHWATER OLIGOCHAETE, STYLODRILUS HERINGIANUS, IN NATURAL LAKE MICHIGAN SEDIMENTS.
National Oceanic and Atmospheric Administration, Ann Arbor, MI. Great Lakes Environmental Research Lab.
T. J. Keilty, and P. F. Landrum.
Environmental Toxicology and Chemistry ETOCDK, Vol. 9, No. 9, p 1147-1154, September 1990. 9 fig, 1 tab, 19 ref.

Descriptors: *Aquatic populations, *Bioassay, *Bioindicators, *Lake Michigan, *Lake sediments, *Oligochaetes, *Sediment contamination, *Toxicity, *Toxicology, *Water pollution effects, Animal behavior, Chronic toxicity, Laboratory methods, Sediment analysis.

Sediment reworking rate, mortality and organism dry weight were measured for Stylodrilus heringianus in laboratory microcosms. The experiments were designed to identify potential population-specific response differences to mixed (stirred to obtain a more uniform particle size distribution over depth) and unmixed (passively settled) microcosm sediments. Lake Michigan sediments and worms were collected off Benton Harbor, Michigan and Grand Haven, Michigan. The mixed Benton Harbor sediments were toxic to S. heringianus collected from Grand Haven, whereas there were no significant differences in measured responses between mixed and unmixed sediment microcosms for Grand Haven-collected worms exposed to Grand Haven sediments or Benton Harbor-collected worms exposed to Benton Harbor sediments. Note that the mixing of sediments resulted in increased availability of contaminants sorbed to the fine sediment fraction. Because contaminant and oligochaete population data suggest that Grand Haven sediments are less contaminated, the population-specific response suggests that S. heringianus may adapt to the low level long-term stressful conditions (chemical or otherwise). Results also suggest caution and consideration of the history of test organisms in the design and interpretation of toxicity tests. (Author's abstract)

AVOIDANCE OF SELENIUM-TREATED FOOD BY MALLARDS.
Patuxent Wildlife Research Center, Laurel, MD.
G. H. Heinz, and C. J. Sanderson.
Environmental Toxicology and Chemistry ETOCDK, Vol. 9, No. 9, p 1155-1158, September 1990. 1 tab, 8 ref. USFWS/San Joaquin Valley Drainage Program Interagency Agreement 6-AA-20-04170.

Descriptors: *Animal behavior, *Ducks, *Food habits, *Selenium, *Toxicology, *Water pollution effects, Feeding rates, Toxicity, Water birds, Waterfowl.

The first step in understanding whether avoidance of selenium-treated diets in laboratory studies will limit extrapolation of results to the field is to determine why birds avoid these diets in the laboratory. Adult, male mallards (Anas platyrhynchos) were given a choice between a control diet and a diet containing 5, 10 or 20 ppm selenium as selenomethionine dissolved in water and mixed into the diet. At 10 and 20 ppm, selenium-treated diets were avoided. Avoidance appeared to be caused by a conditioned response, probably to illness caused by the selenium and not to an aversion to the taste of the selenium. A comparison of the acceptance by wild birds of selenium in natural foods and laboratory diets is needed. (Author's abstract)

STAGE SPECIFIC TOXICITY OF 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN IN EMBRYOS OF THE JAPANESE MEDAKA (ORYZIAS LATIPES).
Rutgers - The State Univ./UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ. Joint Graduate Program in Toxicology.
J. D. Wisk, and K. R. Cooper.
Environmental Toxicology and Chemistry ETOCDK, Vol. 9, No. 9, p 1159-1169, September 1990. 6 tab, 31 ref. NJ Department of Environmental Protection/USGS D-10407-2-88.

Descriptors: *Dioxins, *Embryonic growth stage, *Fish, *Medaka, *Toxicity, *Toxicology, *Water pollution effects, Acute toxicity, Animal pathology, Fertilization, Liver, Median tolerance limit, Sublethal effects.

Embryos of the Japanese medaka were individually exposed to varying concentrations of (H3)2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in a static, nonrenewal system. The EC50 with 95% confidence interval (C.I.) to prevent hatching was 14(11-17) nanograms (ng) TCDD equivalents/L of water (parts per trillion). The LC50 with 95% C.I. for survival to 3 d posthatch was 9(6-12) ng TCDD equivalent/L. The EC50 with 95% C.I. for embryos with minor lesions and severe, life-threatening lesions were 3.5(1.3-5.7) ng TCDD equivalents/L and 14(12.4-15.6) ng TCDD equivalents/L, respectively. In a separate experiment that was terminated prior to the embryos hatching or dying, the EC50 for lesions was calculated to be 2.2(1.4-3.0) ng TCDD equivalents/L. Based on the amount of TCDD equivalents recovered from dechorionated embryos, the ED50 with 95% C.I. for lesions was calculated to be 0.24 picograms TCDD equivalents/mg of dechorionated embryo weight (parts per billion). When the embryos were exposed to (H3)TCDD with 1 to 2 h after fertilization, no concentration dependent increase in visible lesions was observed until after the formation of the liver rudiment (day 4 of development). By exposing Japanese medaka embryos to lethal concentrations of TCDD beginning on different days of embryonic development, it was demonstrated that the sensitive period for toxicity was during liver formation on day 4 or 5 of development. The sensitive period for development was not caused by differences in TCDD absorption across the chorion. When embryos were exposed to (H3)TCDD prior to, during or after liver formation, there was no statistical difference in the dose of TCDD equivalents that crossed the chorion and entered the yolk and embryo. Descriptors: *Acute toxicity, *Bioaccumulation, *Chronic toxicity, *Daphnia, *Kesterson Reservoir, *Midges, *Selenium, *Toxicology, *Water pollution effects, California, Chlorides, Food chains, Larval growth stage, Magnesium, Potassium, Sodium, Toxicity, Trace metals.

Elevated concentrations of Se have been previously measured in biota sampled from the Kesterson National Wildlife Refuge (KNWR) in the San Joaquin Valley of central California. Acute and chronic toxicity tests were conducted with the cladoceran Daphnia magna and the midge Chironomus riparius to determine the toxicity or bioaccumulation of waterborne Se in a reconstituted water similar to the San Joaquin River. Daphnids were more acutely sensitive than midges to the effects of inorganic Se. An organic form of Se (seleno-(L)-methionine) was extremely toxic to daphnids, but was relatively nontoxic to midges. In long-term exposure to a 6:1 mixture of selenate to selenite (a mixture representative of KNWR), the emergence time of adult midges was delayed at Se concentrations >= 837 micrograms/L. Daphnid reproduction and intrinsic rate of natural increase (r) were reduced at Se concentrations >=348 micrograms/L and growth of adults were reduced at >= 156 micrograms/L. Whole body Mg, K and Na concentrations in daphnids were not affected by chronic Se exposure; however, whole body Ca concentration increased at intermediate Se exposure concentrations. In addition, whole body Cl concentration was reduced at 711 micrograms Se/L. Daphnids accumulated potentially toxic concentrations of Se from water that may adversely affect fish or waterfowl through the food chain. (Author's abstract)

SUMMARY OF BIOLOGICAL INVESTIGATIONS RELATING TO SURFACE-WATER QUALITY IN THE KENTUCKY RIVER BASIN, KENTUCKY.
Geological Survey, Reston, VA. Water Resources Div.
L. D. Bradfield, and S. D. Porter.
Available from Books and Open File Report Section, USGS, Box 25425, Denver, CO 80225. USGS Water-Resources Investigations Report 90-4051, July 1990. 63p, 7 fig, 1 tab, 205 ref.

Descriptors: *Algae, *Aquatic insects, *Bioindicators, *Biological communities, *Ecology, *Kentucky River, *Mine drainage, *Water pollution effects, Benthic fauna, Benthic flora, Brines, Mussels, Pollutant identification, Stream fisheries.

The Kentucky River basin, an area of approximately 7,000 sq mi, is divided into five hydrologic units that drain parts of three physiographic regions. Data on aquatic biological resources were collected and reviewed to assess conditions in the major streams for which data were available. The North, Middle, and South Forks of the Kentucky River are in the Eastern Coal Field physiographic region. Streams in this region are affected by drainage from coal mines and oil and gas operations, and many support only tolerant biotic streams. The Kentucky River from the confluence of the three forks to the Red River, is in the Knobs physiographic region. Oil and gas production operations and point discharges from municipalities have affected many streams in this region. The Red River, a Kentucky Wild River, supported a unique flora and fauna but accelerated sedimentation has eliminated many species of mussels. The Millers Creek drainage is affected by brines discharged from oil and gas operations, and some reaches support only halophilic algae and a few fish. The Kentucky River from the Red River to the Ohio River is in the Bluegrass physiographic region. Heavy sediment loads and sewage effluent from urban centers have limited the aquatic biota in this region. Silver Creek and South Elkhorn Creek have been particularly affected and aquatic communities in these streams are dominated by organisms tolerant of low dissolved oxygen concentrations. Biological data for other streams indicate that habitat and water quality conditions are favorable for most commonly occurring aquatic organisms. (USGS)

Descriptors: *Land disposal, *Municipal wastes, *Puerto Rico, *Sewage sludge, *Sludge disposal, *Water pollution effects, Crop yield, Oxisol, Soil types, Vertisol.

Application of municipal sewage sludge to agricultural land is one means of disposing of this material. In general, no important negative effects on either quality of fruit, grain, or forage was observed in this study involving two soil types (one Oxisol and one Vertisol) representing northwestern and southwestern Puerto Rico. Sorghum, pigeon pea (Vertisol site), and eggplant (Oxisol) were grown in field experiments using from 0 to 24 mg/ha of aged Ponce municipal sludge. Yields were determined and leaf, fruit, grain and soils were analyzed. Sludge tended to increase yields and increases in iron concentration in sorghum grain and zinc concentration in pigeon pea are seen as positive effects on quality. Nickel content increased in the leaf tissue of the sorghum while it decreased in the eggplant fruit tissue. Positive effects on exchangeable bases, pH, and available phosphorus, copper, and zinc were seen for the soils, consistent with earlier findings on a Ultisol treated with the same type of sewage sludge. This sludge appears to be a useful amendment for agricultural crops in western Puerto Rico. (USGS)

Descriptors: *Isotope studies, *Neuse River, *Nitrates, *Nitrogen, *Path of pollutants, Algae, Cyanophyta, Cycling nutrients, Eutrophication, Fate of pollutants, Isotopes, Nonpoint pollution sources, North Carolina, Nuisance algae, Pollutant identification, Water pollution effects.

Stable nitrogen isotopic analyses were conducted on dissolved nitrate in surface water samples collected over a two-year period from the lower Neuse River, North Carolina, to assess temporal variation of nitrate sources to the watershed. Nitrate samples collected at the Raleigh and Durham Municipal Sewage Treatment Plants have nitrogen isotopic values in the +9 to +14/mil range. Nitrate samples collected from agricultural drainage areas in the lower portion of the Neuse River basin have nitrogen isotopic values in the +4 to +9/mil range. These nitrogen isotopic values correspond well to literature values published for point and nonpoint nitrate sources, respectively, and confirm that there is a well defined isotopic difference between point and nonpoint nitrate inputs to the Neuse River Basin. The nitrogen isotopic values of nitrate from the lower Neuse, which integrates the nutrient loading trends over the entire basin, show an annual cycle. Surface water nitrate during low discharge periods is isotopically enriched and is in the point range of +9 to +14/mil. Surface water nitrate collected during high discharge periods is isotopically depleted and is in the nonpoint source range of +4 to +9/mil. Over the entire annual hydrological cycle, surface water nitrate nitrogen isotopic values are exponentially related to river discharge rate. This relationship suggests that a residence time delay factor in an intermediate reservoir (groundwater, wetlands) plays an important role in the transfer of nonpoint source nitrate to the riverine system during the falling discharge (spring) period. The enhanced fertilizer loading in wet years during the critical spring period can influence the biological species succession and would therefore play a significant role in enhancing nuisance algae bloom potential in late summer. PHOSPHORUS CYCLE AND ITS SIGNIFICANCE IN THE EUTROPHICATION OF LAKE SEVAN.
Akademiya Nauk Armyanskoi SSR, Sevan. Hydrobiological Station.
R. M. Parparova.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 709-712, 1990. 3 tab, 7 ref.

Descriptors: *Cycling nutrients, *Eutrophic lakes, *Eutrophication, *Lake Sevan, *Limnology, *Phosphates, *Phosphorus, *Water pollution effects, Diffusion, Lake sediments, Organic compounds, Orthophosphates, Plankton, Pore water, Precipitation, Primary productivity, Sedimentation, Surface water, USSR, Vertical stratification.

Eutrophication of Lake Sevan caused by its artificial level lowering has resulted in sharp changes in the nutrient regime. Tributaries are rich in P, due to geological peculiarities of the lake basin, with orthophosphate the main form of P. There is a positive relation between yearly average concentrations of total P and orthophosphate. During the last 50 years input of P from the basin to Lake Sevan had a small increase, from 133 to 150 t/yr. (The content of P in snow and rain increased almost two-fold.) Almost half of the P of tributaries and rain water is orthophosphate. The P concentration of the lake is determined by the concentration of its organic form to a much greater degree than in the river water. An increase in

vertical stratification of orthophosphate is an important consequence of eutrophication. Unlike many lakes, P in Lake Sevan consists mainly of dissolved forms. Mineral and organic compounds make up approximately equal parts of dissolved P. The concentration of P in pore water exceeds that of surficial water by 1-2 orders of magnitude. Internal processes (diffusion from bottom and sedimentation) are the most significant components of the P budget; external components (tributaries and precipitation) are insignificant. Excess of P sedimentation over its diffusion from the bottom is not compensated by discharge from the lake basin. This has caused a decreasing P concentration in the lake for many years. Lowering of the level of the lake itself could destroy the P cycle. Under a decreasing mean depth more of the P store in the water column is sedimented. Eutrophication of the lake in conjunction with the lowering led to a relative increase of particulate P and consequent increase in sedimentation. Resuspension of particulate matter as a result of lake lowering should also contribute to P sedimentation as a result of its sorption on resuspended particles. An increase of plankton primary production under a decreasing P concentration is a peculiarity of the eutrophication of Lake Sevan. Internal processes (sedimentation and diffusion from the bottom) should determine the P regime of the lake in the near future. (Sand-PTT)

EUTROPHICATION OF NIGERIA'S LAKE ASEJIRE.
Benin Univ., Benin City (Nigeria). Dept. of Zoology.
A. B. M. Egborge.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 793-802, 1990. 8 fig, 15 ref.

Descriptors: *Enrichment, *Eutrophication, *Limnology, *Nigeria, *Nutrients, *Reservoirs, *Water pollution effects, Dissolved oxygen, Hydrogen ion concentration, Lake Asejire, Nitrates, Phosphates, Stratification, Water temperature.

Thirteen years after the inundation of the River Oshum to form Lake Asejire, the three phases of impoundment have been completed. An increase in nutrient levels, indicated by conductivity, progressed steadily until 1978. Five years later, although the general nutrient load was similar to that of 1978, its vertical distribution showed a stratification with more nutrients in the bottom strata. Between 1978 and 1983 there were also significant increases in temperature, pH, and particularly phosphate, which showed a 200% increase over its 1975/76 levels. Increases in phosphate levels associated with marked decreases in nitrate-N and dissolved oxygen content are indications of a deteriorating lake environment. (Author's abstract)

INFLUENCE OF CAGE REARING PISCICULTURE ON WATER QUALITY AND BOTTOM SEDIMENTS IN ARTIFICIAL LAKES.
KNIPIBKS Vodokanalproject, Sofia (Bulgaria). Dept. of Scientific and Technological Research.
V. Semov, and A. Kuntcheva.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 875-879, 1990. 1 fig, 2 tab, 6 ref.

Descriptors: *Artificial lakes, *Bottom sediments, *Carp, *Fish farming, *Lake sediments, *Path of pollutants, *Water pollution effects, *Water pollution sources, Antonivanovtzi Dam, Bulgaria, Detritus, Hydrogen sulfide, Iron, Manganese, Nitrogen, Organic matter, Oxygen, Phosphorus, Water quality.

Studies were carried out on water quality and bottom sediments in the Antonivanovtzi Dam in Bulgaria, where carp are reared in cages. During periods of maximum fish yield, the quantity of discharged organic matter as scattered (non-utilized) food is more than 1400 tons annually. The pollution impact of cage rearing pisciculture most distinctly affects the bottom sediments, leading to a significant increase in their oxygen uptake rates. The oxygen uptake by bottom sludges in the Antonivanovtzi Dam cage rearing farm zone, expressed in mg O2/1 gm dry sediment for a 24-hr period, is 7.0, and by sediments in the upper part of the lake, outside the cage rearing zone, only 1.8 mg O2. The loss on ignition value, the total N, organic N and total P values, expressed in % of the dry sediments in the samples from the cage rearing zone, are respectively 13.70, 1.18, 0.78, and 0.47, against 10.37, 0.19, 0.14, and 0.07 in samples from the upper part of the lake. The raised consumption of oxygen at the bottom is the cause of anaerobic hypolimnion formation in the dam, starting in July and August, and lasting until the autumn vertical circulation of water begins. Within the rotting organic matter, under anaerobic conditions, hydrogen sulfide is formed, and accumulates in the bottom layers. Iron, manganese and phosphorus also change to soluble forms and accumulate in the water layer, entering the circle of matter. With the aim of preserving the natural water regime and the biological equilibrium in the Antonivanovtzi Dam as a potential water supply source, it was recommended that cage rearing pisciculture be eliminated or reduced to a minimum. GROWTH, PRODUCTION, AND DECOMPOSITION DYNAMICS OF SPHAGNUM UNDER NATURAL AND EXPERIMENTALLY ACIDIFIED CONDITIONS.
Alberta Univ., Edmonton. Dept. of Botany.
L. Rochefort, D. H. Vitt, and S. E. Bayley.
Ecology ECOLAR, Vol. 71, No. 5, p 1986-2000, October 1990. 6 fig, 6 tab, 74 ref. Natural Sciences and Engineering Research Council of Canada grant A-6390.

Descriptors: *Acid rain effects, *Acidification, *Decomposition, *Mosses, *Peat bogs, *Plant growth, *Primary productivity, *Sphagnum, Acid rain, Acidic water, Canada, Environmental effects, Growth rates, Nitrates, Ontario, Peat, Sulfates, Water pollution effects.

Annular linear growth, net primary production, and decomposition of Sphagnum fuscum, Sphagnum magellanicum, and Sphagnum angustifolium were measured under experimental acidification and natural conditions in a poor fen at the Experimental Lakes Area, Ontario, Canada. For the experiment, the mire received two treatments: a control area was sprayed with lake water only and an acidified area was sprayed with lake water plus strong acids to simulate acidic rain equivalent to a pH of 4.0. Acidification increased growth and production of most species (2 out of 3 in the oligotrophic zone, and 2 out of 3 in the minerotrophic zone) in the first 2 years. After 2-3 years of artificial acidification, growth and production were not stimulated to the same extent in experimental areas as in earlier years. After 4 years, growth and production in the experimental area declined so that they were the same as controls for 4 of the 6 treatments. Therefore, the effect of the acid treatment changed over the years. With 4-year simulated acid rain, decomposition was unaffected. Our results suggest that the fertilizing effect of SO4(2-) and NO3(-) in North American acid precipitation as suggested previously in the literature is a very short-term one, a least for this type of peatland. Under natural conditions, in the oligotrophic central zone of the mire, production for hollow species was somewhat greater than for hummock species for the 4 years studied. Since the decomposition rate ratio between hummock-top, mid-hummock, and hollow species is roughly in the ratio 7:9:13, the rate of peat accumulation should be higher in hummocks. Hence hummocks appear to be maintained in this poor fen due to low decomposition rates rather than relatively high production. The relative decomposition rates of the species in the minerotrophic edge zone had the same ratio as in the oligotrophic zone. Thus hummocks appear to be expanding in this minerotrophic edge zone at a faster rate than in the oligotrophic zone. (Mertz-PTT)

ELEVATED ATMOSPHERIC CO2 EFFECTS ON BELOWGROUND PROCESSES IN C3 AND C4 ESTUARINE MARSH COMMUNITIES.
Smithsonian Environmental Research Center, Edgewater, MD.
P. S. Curtis, L. M. Balduman, B. G. Brake, and D. F. Whigham.
Ecology ECOLAR, Vol. 71, No. 5, p 2001-2006, October 1990. 4 fig, 1 tab, 26 ref.

Descriptors: *Air pollution effects, *Carbon dioxide, *Climatic changes, *Estuarine environment, *Greenhouse effect, *Marsh plants, *Salt marshes, *Wetlands, Air pollution, Cord grasses, Ecological effects, Growth rates, Marshes, Nitrogen, Roots, Sedges.

Recent work on the responses of native perennial plants to elevated CO2 has begun to explain the ecological consequences of rising atmospheric CO2. It has been shown that plants have a wide range of aboveground morphological and physiological responses to high CO2. Belowground carbon allocation is a major component of a plant's carbon budget, yet relatively little is known about the response of roots to elevated atmospheric CO2. Three brackish marsh communities dominated by perennial macrophytes were exposed to twice ambient CO2 concentrations for two full growing seasons using open top chambers. One community was dominated by the C3 sedge Scirpus olneyi, one was dominated by the C4 grass Spartina patens, and one was a mixture of S. olneyi, S. patens, and Distichlis spicata, a C4 grass. Root and rhizome growth were studied in the second year of exposure by measuring growth into peat cores previously excavated and refilled with sphagnum peat devoid of roots. Growth under elevated CO2 resulted in an 83% increase in root dry mass per core in the Scirpus community. Those roots were also significantly lower in percentage of nitrogen than roots from ambient-grown plants. There was no effect of elevated CO2 on root growth or nitrogen content in the Spartina community or in the C4 component of the mixed community. (Mertz-PTT)

PREDATION ON AMPHIBIAN EGGS AND TADPOLES BY COMMON PREDATORS IN ACIDIFIED LAKES.
Goeteborg Univ. (Sweden). Dept. of Zoology.
B. I. Henrikson.
Holarctic Ecology HOECD2, Vol. 13, No. 3, p 201-206, August 1990. 3 tab, 43 ref.

Descriptors: *Acid rain effects, *Acidification, *Amphibians, *Eggs, *Lake acidification, *Larval growth stage, *Predation, Acid rain, Acidic water, Aquatic insects, Dragonflies, Ecological effects, Frogs, Newts, Toads, Water beetles, Water boatmen, Water bugs.

During the last few decades, the large-scale acidification of surface waters has been shown to be a threat to amphibians inhabiting even non-agricultural areas. The negative impact of chemical changes to amphibian eggs and larvae such as low pH and high aluminum content is documented in both field and laboratory studies. In an attempt to determine potential predators on moor frog, Rana arvalis and common toad, Bufo bufo eggs in acidified lakes and the palatability of eggs and tadpoles researchers offered eggs and three different stages of premetamorphic tadpoles to the following potential predators in acidified lakes: newt Triturus vulgaris, water beetles Rhantus exoletus and Dytiscus lapponicus, dragonfly larvae Leucorrhinia dubia and Aeshna spp., water boatman Notonecta glauca and water bugs, Cymatia bonsdorffi, Glaenocorisa p. propinqua, and Corixa dentipes. The predation pressure on eggs of R. arvalis was low due to thick jelly. The eggs of B. bufo were not attractive to predators with chewing mouth parts due to unpalatability but predators with sucking mouth parts were not repulsed. Tadpoles of R arvalis were eaten by all predators but tadpoles o

B. bufo were unpalatable to most predators. The predators used in the experiments are the new top predators in acidified fishless lakes. They may contribute to the reduction of populations of R. arvalis in acidified areas. (Mertz-PTT)

PREMATURE THELARCHE IN PUERTO RICO: A SEARCH FOR ENVIRONMENTAL ESTROGENIC CONTAMINATION.
Centers for Disease Control, Atlanta, GA. Center for Environmental Health.
W. H. Hannon, R. H. Hill, J. T. Bernert, L. Haddock, and G. Lebron.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 3, p 255-262, May 1987. 1 fig, 3 tab, 28 ref.

Descriptors: *Chlorinated hydrocarbons, *Hormones, *Human physiology, *Premature thelarche, *Public health, *Puerto Rico, *Water pollution effects, Centers for Disease Control, Chemical analysis, Drinking water, Foods, Gas chromatography, Hormone supplementation, Laboratory methods, Mass spectrometry, Pesticides, Water analysis, Water pollution sources.

Premature thelarche is usually defined as breast development in girls below the age of eight years without other signs of premature sexual development. This condition is usually viewed as a variation in maturation or ovarian sensitivity, and is regarded as a benign condition that is not the beginning phase of a more serious problem. The etiology and population incidence are unknown. As part of an investigation into the cause of premature thelarche in Puerto Rico, the Centers for Disease Control (CDC) conducted various laboratory analyses to screen for estrogenic sources. Samples were obtained from case and control households, children, parents, and environmental sources. Serum samples were analyzed from parents and children and household water samples for chlorinated hydrocarbons and no results were found above normal. Using gas chromatography/mass spectroscopy (GC/MS) procedures, serum was analyzed for zearalonol and its derivatives. Four case samples from the residual sample set were reported presumptively positive for zearalonol. Analyses of 96 case samples for estradiol, follicle-stimulating hormone (FSH) and luteinizing hormone (LH) yielded values within the normal reference range. The rat uterine cytosol-receptor assay was used as nonspecific screen for estrogenic activity. Two different contract laboratories used this assay to analyze milk, meat, poultry, and water samples collected from the households and local markets. The reliability of this assay was dependent upon the type of sample matrix. No significant difference between case and control samples was found with this screening process. (Author's abstract)

ACUTE TOXICITY OF AQUEOUS AND SUBSTRATE-BOUND COPPER TO THE MIDGE, CHIRONOMUS DECORUS.
California Univ., Davis. Dept. of Land, Air and Water Resources.
P. Kosalwat, and A. W. Knight.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 3, p 275-282, May 1987. 4 fig, 3 tab, 33 ref. EPA Cooperative Agreement No. CR-808424 and Lawrence Livermore National Laboratory Intramural Order No. 4383305.

Descriptors: *Bioassay, *Biological magnification, *Copper, *Larvae, *Midges, *Toxicity, *Toxicology, *Water pollution effects, Bioconcentration factor, Chemical analysis, Chemical interactions, Chemical properties, Chemical speciation, Experimental data, Experimental design, Larval growth stage, Substrates, Water analysis.

Fourth instar larvae of the midge, Chironomus decorus, were exposed to copper in water and copper in food and substrate (bound forms). Copper present in aqueous forms was more toxic than when it was present in bound forms. The relationship between copper in water and copper in midges could be described by an exponential equation while the relationship between copper in substrate and midges was best described by a simple linear regression equation. Midge larvae accumulated copper from water and possessed some mechanisms to regulate copper uptake and excretion when exposed to copper concentrations of 0.05-1.0 mg/L (aqueous forms) and lost that ability when the concentration exceeded 1.0 mg/L. On the contrary, the midge larvae were unable to accumulate copper from food, since the estimated bioconcentration factor was between 0.10 and 0.16. When the midge larvae were exposed to copper in water, the uptake rate increased rapidly from 0-10 hr and then the rate increased very slowly or in some cases it reached a steady state after 10 hr. The steady state was attained within 1 to 3 hr when the midges were exposed to copper in food and substrate. (See also W91-02431) (Author's abstract)
W91-02430

CHRONIC TOXICITY OF COPPER TO A PARTIAL LIFE CYCLE OF THE MIDGE, CHIRONOMUS DECORUS.
California Univ., Davis. Dept. of Land, Air and Water Resources.
P. Kosalwat, and A. W. Knight.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 3, p 283-290, May 1987. 5 fig, 1 tab, 33 ref. EPA Cooperative Agreement CR-808424 and Lawrence Livermore National Laboratory Intramural Order No. 4383305.

Descriptors: *Chronic toxicity, *Copper, *Eggs, *Embryonic growth stage, *Larvae, *Larval growth stage, *Midges, *Sublethal effects, *Teratogenic effects, *Toxicity, *Water pollution effects, Bioassay, Hatching, Incubation, Sediment contamination, Statistical analysis, Substrates.

A study was undertaken to evaluate the sublethal effects of sediment copper on the life history of the midge Chironomus decorus. The development and hatchability of C. decorus eggs were not affected by 0.1 to 5 mg/L of copper in water. The embryos developed normally and hatched at about the same time (after 55 hr of incubation). All larvae survived the duration of the test (72 hr) except those subjected to 5 mg/L of copper in water, which died after only partial emergence from the egg shell. Apparently, eggs were protected by their shell from copper. Growth of C. decorus larvae was reduced significantly when they were reared in copper-spiked food-substrate (bound copper) from the age of 1 to 15 days old (900-4500 mg/kg of copper). The substrate copper concentration at which larval growth was reduced to 50% (EC50) was 1,602 mg/kg. Substrate copper caused deformities in the epipharyngeal plate of larval mouthparts and copper concentrations higher than 1800 mg/kg delayed adult emergence. The copper concentration in pupal exuviae and adults were positively correlated to copper concentrations in the substrate in which they had been reared as larvae. Larval stage appeared to be the most sensitive to copper toxicity, while eggs were the least sensitive. Larval growth was the best indicator in detecting copper pollution, since it could detect copper at relatively low concentrations. The time to adult emergence was not considered a very good indicator, while larval deformities offered a quick tool to evaluate copper pollution. (See also W91-02430) (Author's abstract)

TOXIC EFFECTS OF TETRAETHYL LEAD AND ITS DERIVATIVES ON THE CHRYSOPHYTE POTERIOCHROMONAS MALHAMENSIS: VIII. COMPARATIVE STUDIES WITH SURFACTANTS.
Hohenheim Univ., Stuttgart (Germany, F.R.). Inst. fuer Botanik.
G. Roderer.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 3, p 291-301, May 1987. 7 fig, 2 tab, 39 ref.

Descriptors: *Algae, *Algal growth, *Chrysophyta, *Cytology, *Lead, *Lethal limit, *Organometals, *Surfactants, *Toxicity, *Toxicology, *Water pollution effects, Algal physiology, Assay, Cytolysis, Flagellates, Germany, Lipids, Microtubules, Poteriochromonas malhamensis, Tetraethyl lead, Triethyl lead.

The toxic effect of triethyl lead (TriEL) on the phytoflagellate Poteriochromonas malhamensis (Chrysophyceae) was compared with those of eight surfactants some of which represent environmental pollutants. The surfactants typically inhibited algal growth and caused cytolysis in the concentration range from 12-310 microM. TriEl was cytolytic, similar to the surfactants, while lethal concentrations of inorganic lead did not cause cytolysis. It is postulated that this cytolytic effect was mainly governed by combined hydrophobic and electrostatic interactions with the lipid phase of the membranes. The cationic and zwitterionic surfactants and sodiumdodecylsulfate (SDS) and TriEL selectively inhibited mitosis and cytokinesis of the alga and caused the formation of giant multinucleated cells, suggesting selective interaction on the algal microtubules (MTs). However, sodiumdeoxycholate (DOC), Triton X-100 (TX100), and Triton X-405 (TX405) had no selective effects on these parameters. The most active surfactant, SDS, inhibited MT assembly in vitro and caused an instant and complete disassembly is applied to MTs that were preassembled without surfactant. TX100, which was inactive in the algae, showed no effect in the in vitro MT assay, even is applied in ten times higher concentrations than SDS. The observations indicate that the surfactants did not act chaotropically on the alga's cell membranes and that not only TriEL, but also the active surfactants selectively interfered with MTs, resulting in their selective toxic action in P. malhamensis. TRIBUTYLTIN RETARDS REGENERATION AND PRODUCES DEFORMITIES OF LIMBS IN THE FIDDLER CRAB, UCA PUGILATOR.
Rutgers - The State Univ., Newark, NJ. Dept. of Biological Sciences.
J. S. Weis, J. Gottlieb, and J. Kwiatkowski.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 3, p 321-326, May 1987. 4 fig, 1 tab, 23 ref.

Descriptors: *Antifoulants, *Crabs, *Organotin compounds, *Toxicity, *Toxicology, *Water pollution effects, Aquatic animals, Aquatic environment, Aquatic life, Crustaceans, Ecdysis, Hormesis, Marine animals, Marine environment, Marine pollution.

Treatment of fiddler crabs, Uca pugilator, with levels of tributyltin (TBT) as low as 0.5 micro g/L during limb regeneration resulted in a retardation of the regenerative growth and a delay in ecdysis at the end of the regeneration process. Limbs regenerated in the presence of TBT showed a variety of deformities, primarily a curved appearance. This was particularly apparent in regenerated chelae, in which the dactyl curved away from, rather than towards, the pollex. The number of setae was reduced in limbs that regenerated in TBT, compared to those that regenerated in clean sea water, which in turn had a reduced number of setae in comparison to intact limbs. The production of deformities in the regenerated limbs was the most sensitive response and is consistent with findings in other groups of organisms, in which TBT also produces morphological abnormalities. TOXICITY OF CHLORINATED BORNANE (TOXAPHENE) RESIDUES ISOLATED FROM GREAT LAKES LAKE TROUT (SALVELINUS NAMAYCUSH).
Michigan State Univ., East Lansing. Pesticide Research Center.
J. W. Gooch, and F. Matsumura.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 16, No. 3, p 349-355, May 1987. 3 fig, 3 tab, 33 ref. Michigan Sea Grant Program Grant No. NA84AA-D-SG045C.

Descriptors: *Bioassay, *Great Lakes, *Insecticides, *Lakes, *Path of pollutants, *Pesticide residues, *Pesticide toxicity, *Tissue analysis, *Toxaphenes, *Toxicity, *Toxicology, *Trout, *Water pollution effects, Aquatic animals, Aquatic environment, Aquatic life, Fish, Laboratory methods, Water pollution, Water sampling.

Lake trout samples from the Great Lakes contain residues of a complex pattern of chlorinated bornanes similar to the insecticide toxaphene. These residues, although structurally similar to toxaphene, are composed of a different profile of compounds than the analytical standard. Chlorinated bornane residues were isolated from tissues of Lake Michigan and Siskiwit Lake (Isle Royale) lake trout using a variety of purification techniques. Toxicity studies were conducted to determine the toxicological properties of the isolated residues in comparison to both technical material and the procedural standard. Static 24-hr acute bioassays with mosquito larvae (Aedes egypti) demonstrated that the residues were as toxic as the toxaphene standard. Additionally, experiments performed on the picrotoxinin receptor of the GABA (gamma-aminobutyric acid)-chloride ionophore complex of the central nervous system revealed that the residues were very potent at the 35S-t-butylbicyclophosphorothionate binding site. Therefore, both non-specific and specific measures of toxicologic potency show that environmentally derived residues of toxaphene retain significant biologic activity. There is no trend for decreasing toxicity of toxaphene residues for the period of 1982-85. Also, the residues found in samples from Siskiwit Lake were as toxic as those found in Lake Michigan. EFFECTS OF CHLORINATED BENZENES ON DIATOM FATTY ACID COMPOSITION AND QUANTITATIVE MORPHOLOGY: I. 1,2,4-TRICHLOROBENZENE.
Michigan Univ., Ann Arbor. Great Lakes Research Div.
L. Sicko-Goad, D. Lazinsky, J. Hall, and M. S. Simmons.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 18, No. 5, p 629-637, September 1989. 7 fig, 1 tab, 31 ref. US EPA Grant No. R-810684.

Descriptors: *Benzenes, *Bioaccumulation, *Biological magnification, *Chlorinated hydrocarbons, *Diatoms, *Fatty acids, *Lipids, *Morphology, *Path of pollutants, *Structure-activity relationships, *Toxicity, *Toxicology, *Water pollution effects, Aromatic compounds, Correlation analysis, Experimental design, Lipophilicity, Octanol/water partition coefficients, Photosynthesis, Trichlorobenzenes.

It is believed that there is a correlation between the uptake of chlorinated hydrocarbons by organisms and their lipid contents. It has also been demonstrated that exposure to hydrophobic compounds may result in changes in fatty acid composition. A series of studies was undertaken to determine the effect of selected chlorinated benzenes on diatom fatty acid composition and cell structure. This study hopes to determine that, under similar controlled environmental conditions, observed sensitivity parallels that predicted by environmental chemistry. Cells of the diatom Cyclotella meneghiniana were exposed in a closed system to 0.245 ppm 1,2,4-Trichlorobenzene. Response to this chlorinated benzene was monitored over a period of 5 days by quantitative ultrastructure and fatty acid percent composition. Over the time period examined, 41 significant morphological changes and 12 significant changes in fatty acid composition were observed. Autophagic-like vacuoles were frequently observed, indicating lysis of cellular constituents. In general, there was an increase in the C20:5 fatty acid, which may be indicative of photosynthetic impairment, since this fatty acid probably substitutes for linolenic acid in diatoms. The most significant numbers of changes were observed after 8 hr of exposure to this lipophilic toxicant, and these changes occurred in membranous organelles. It is suggested that the daily photoperiodic variation in lipid content of phytoplankton may be an important consideration in evaluating effects of lipophilic toxicants. (See W91-02437 thru W91-02439) (Korn-PTT)
W91-02436

EFFECTS OF CHLORINATED BENZENES ON DIATOM FATTY ACID COMPOSITION AND QUANTITATIVE MORPHOLOGY: II. 1,3,5-TRICHLOROBENZENE.
Michigan Univ., Ann Arbor. Great Lakes Research Div.
L. Sicko-Goad, J. Hall, D. Lazinsky, and M. S. Simmons.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 18, No. 5, p 638-646, September 1989. 7 fig, 1 tab, 29 ref. US EPA Grant No. R-810684.

Descriptors: *Benzenes, *Bioaccumulation, *Biological magnification, *Chlorinated hydrocarbons, *Diatoms, *Fatty acids, *Lipids, *Morphology, *Path of pollutants, *Structure-activity relationships, *Toxicity, *Toxicology, *Water pollution effects, Aromatic compounds, Correlation analysis, Experimental design, Lipophilicity, Octanol/water partition coefficients, Photosynthesis, Trichlorobenzenes.

It has been suggested that increased toxicity of more octanol-soluble compounds to unicellular green algae may be related either to the greater ability of these compounds to penetrate and damage the lipoprotein cell membrane or to overall lipid content of the algae. Cells of the diatom Cyclotella meneghiniana were exposed in a closed system to 0.245 ppm 1,3,5-trichlorobenzene. Response of the diatom was measured by quantitative ultrastructure and fatty acid percent composition over a 5-day period. During that time, 28 significant morphological and 13 significant fatty acid percent composition changes occurred. Autophagic-like vacuoles were observed consistently through the sampling periods. In comparison with exposure to 1,2,4-trichlorobenzene, 1,3,5-trichlorobenzene exerts fewer effects in the parameters studied, and these effects were observed most frequently in membranous components during the initial eight hours of exposure. It is suggested that the amount of cellular lipid and the relative reactivity of the isomer are responsible for the observed effects. (See W91-02436, W91-02438, and W91-02439) (Author's abstract)
W91-02437

EFFECTS OF CHLORINATED BENZENES ON DIATOM FATTY ACID COMPOSITION AND QUANTITATIVE MORPHOLOGY: III. 1,2,3-TRICHLOROBENZENE.
Michigan Univ., Ann Arbor. Great Lakes Research Div.
L. Sicko-Goad, J. Hall, D. Lazinsky, and M. S. Simmons.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 18, No. 5, p 647-655, September 1989. 8 fig, 1 tab, 32 ref. US EPA Grant No. R-810684.

Descriptors: *Benzenes, *Bioaccumulation, *Biological magnification, *Chlorinated hydrocarbons, *Diatoms, *Fatty acids, *Lipids, *Morphology, *Path of pollutants, *Structure-activity relationships, *Toxicity, *Toxicology, *Water pollution effects, Aromatic compounds, Correlation analysis, Experimental design, Lipophilicity, Octanol/water partition coefficients, Photosynthesis, Trichlorobenzenes.

Cells of the diatom Cyclotella meneghiniana were exposed in a closed system to 0.245 ppm 1,2,3-trichlorobenzene. Response of the diatom was measured by quantitative ultrastructure and fatty acid percent composition over a 5-day period. During that time, 35 significant morphological and 12 significant fatty acid percent composition changes occurred. The most pronounced morphological change that occurred was a significant increase in lipid volume. In addition, changes were observed in vacuolar relative volume, suggesting that the tonoplast became more permeable. Fewer significant changes were observed in fatty acid percent composition upon exposure to this isomer. However, there was a consistent increase in oleic acid (C18:1). The observed changes in morphological and fatty acid percent composition were uniformly distributed with time after the first hour of exposure. Results support the hypothesis that increased lipid stores alter the timing of response to lipophilic toxicants. (See W91-02436, W91-02437, and W91-02439) (Author's abstract)
W91-02438

EFFECTS OF CHLORINATED BENZENES ON DIATOM FATTY ACID COMPOSITION AND QUANTITATIVE MORPHOLOGY: IV. PENTACHLOROBENZENE AND COMPARISON WITH TRICHLOROBENZENE ISOMERS.
Michigan Univ., Ann Arbor. Great Lakes Research Div.
L. Sicko-Goad, M. S. Evans, D. Lazinsky, J. Hall, and M. S. Simmons.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 18, No. 5, p 656-668, September 1989. 12 fig, 1 tab, 28 ref. US EPA Grants No. R-810684 and R-812311.

Descriptors: *Benzenes, *Bioaccumulation, *Biological magnification, *Chlorinated hydrocarbons, *Diatoms, *Fatty acids, *Lipids, *Morphology, *Path of pollutants, *Structure-activity relationships, *Sublethal effects, *Toxicity, *Toxicology, *Water pollution effects, Aromatic compounds, Correlation analysis, Experimental design, Lipophilicity, Octanol/water partition coefficients, Pentachlorobenzene, Photosynthesis, Trichlorobenzenes.

Cells of the diatom Cyclotella meneghiniana were exposed in a closed system to 0.095 ppm pentachlorobenzene over a period of 5 days. Changes in fatty acid and morphological percent composition were monitored to determine the effect of the toxicant. The greatest morphological change observed was an increase in lipid volume. Most morphological changes occurred in the 1 hour and 5 day sampling periods. Few changes in morphological characteristics or fatty acid percent compositions were observed at eight hours, when the cells were in the dark. The C18:1 and C20:5 fatty acids were most variable with exposure to pentachlorobenzene. Results suggest that at sublethal doses, lipophilic toxicants exert effects that are biphasic. That is, immediately measurable effects are observed in the cells that include increases in storage products and changes in membranous organelles. Long-term effects are postulated to be the result of mobilization of lipophilic toxicants that have partitioned into lipid stores and are more available when lipids are metabolized. Although pentachlorobenzene has a higher octanol/water partition coefficient, it appears to exert fewer cellular changes than any trichlorobenzene isomer. SKELETAL DEFORMITIES IN SMALLMOUTH BASS, MICROPTERUS DOLOMIEUI, FROM SOUTHERN APPALACHIAN RESERVOIRS.
Georgia Cooperative Fishery and Wildlife Research Unit, Athens.
M. J. Van Den Avyle, S. J. Garvick, V. S. Blazer, S. J. Hamilton, and W. G. Brumbaugh.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 18, No. 5, p 688-696, September 1989. 2 fig, 7 tab, 30 ref.

Descriptors: *Animal pathology, *Animal tissues, *Appalachian Mountains, *Black bass, *Fish, *Reservoirs, *Water pollution effects, Aquatic animals, Aquatic environment, Aquatic life, Bioindicators, Contaminant residues, Skeletal deformities.

Smallmouth bass (Micropterus dolomieui) populations in two of five reservoirs sampled in the southern Appalachian Mountains contained high percentages of individuals with lordosis, kyphosis or scoliosis. Deformities of the vertebral column occurred in several year classes and varied with fish size; they were absent in small fish, present in 25-30% of the fish 241-300 mm long, and then decreased in occurrence with increased length

ecause environmental contamination is often re-
onsible for high occurrences of deformed fish,
hole-body concentrations of contaminants, bone
evelopment characteristics, and blood plasma
oncentrations of calcium and phosphorus in
rmal and deformed fish were measured and were
mpared with the results of fish from reservoirs
here no deformed fish were found. Vertebrae
ere significantly weaker and more elastic in de-
rmed that in normal fish, but biochemical prop-
ies of vertebrae were similar among the groups
ted. Concentrations of pesticides and metals
ere not elevated in deformed fish, and concentra-
ns of calcium and phosphorus in blood plasma
ere similar in normal and deformed groups. Most
vironmental contaminants that have been shown
cause fish deformities could be discounted as
sative agents on the basis of these results; how-
er, the exact cause was not determined. Further
empts to diagnose the cause of the deformities
re limited by the lack of background informa-
n on relationships among the bone development
ocesses, types of stresses that cause deformities
types of bone tissue in fish. (Author's abstract)

the 1983 nesting season, Forster's tern (Sterna
eri) reproductive success was significantly im-
ed on organochlorine contaminated Green
Lake Michigan compared to a relatively un-
aminated inland location at Lake Poygan, Wis-
in. Compared with tern eggs from Lake
gan, eggs from Green Bay had significantly
er median concentrations of 2,3,7,8-tetrachlor-
enzo-p-dioxin (TCDD), other polychlorinated
nzo-p-dioxins (PCDDs), total polychlorinated
enyls (PCBs), total (three congeners) non-
, ortho' PCBs, five individual PCB congeners
vn to induce aryl hydrocarbon hydroxylase
H) and several other organochlorine contami-
. Two PCB congeners, 2,3,3',4,4'-, and
,4',5-pentachlorobiphenyl (PeCB) accounted
ore than 90% of the median estimated TCDD
alents at both Green Bay and Lake Poygan.
hatching success of Green Bay sibling eggs
nests where eggs were collected for contami-
analysis was 75% lower at Green Bay than at
Poygan. In both field and laboratory, mean
num incubation periods were significantly
r for eggs from Green Bay compared to Lake
an. Nest abandonment and egg disappearance
substantial at Green Bay but nil at Lake
an. Thus, not only factors intrinsic to the egg,
lso extrinsic factors (Parental attentiveness),
red reproductive outcome at Green Bay. The
miological evidence from this study strongly
sted that contaminants were a casual factor.
-active PCB congeners (intrinsic factors) and
in general (extrinsic effects) appeared to be
nly contaminants at the concentrations meas-
n eggs, capable of producing the effects that
observed at Green Bay. (Author's abstract)

**ACUTE TOXICITY OF INDUSTRIAL SURFAC-
TANTS TO MYSIDOPSIS BAHIA.**

AWARE, Inc., Nashville, TN.
W. S. Hall, J. B. Patoczka, R. J. Mirenda, B. A. Porter, and E. Miller.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 18, No. 5, p 765-772, September 1989. 2 fig, 3 tab, 17 ref.

Descriptors: *Acute toxicity, *Bioindicators, *Crustaceans, *Estuarine environment, *Marine environment, *Opossum-shrimp, *Surfactants, *Toxicology, *Water pollution effects, Aquatic animals, Ethylene oxide, Hazard assessment, Industrial wastes, Lethal limit, Solubility, Water pollution sources.

The estuarine crustacean Mysidopsis bahia has been increasingly used to evaluate the toxicity of pure chemicals, effluents, and drilling muds in estuarine and marine environments. M. bahia is ecologically important due to its utilization as a major food source for bottom feeding fishes. A study was conducted to determine the acute toxicities of a variety of industrial surfactants to M. bahia and to gain some insight as to the importance of different chemical characteristics in influencing the toxicity of each surfactant. Three-day to eight-day old M. bahia were used to evaluate the acute toxicities of 17 industrial surfactants having a wide range of physicochemical characteristics. LC50s, based on nominal concentrations covered approximately three orders of magnitude (<1 to >4,000 mg/L). The base structure of the surfactants (i.e., aromatic, alipathic, branched, or linear) was not a factor controlling toxicity. Low solubility surfactants with low ethylene oxide (EO) molar ratios were the most toxic surfactants tested. Ethylene oxide chain length was the best predictor of toxicity, and would be a good parameter to use to screen for surfactant toxicity in hazard assessment. Substitution of terminal OH with SO3 or PO4 reduced toxicity of a selected group of surfactants. Sensitivity of M. bahia up to 26 days old was not significantly different from that of 3 to 8 day old animals. Use of one surfactant as a reference toxicant demonstrated that sensitivity of M. bahia was consistent throughout the various tests. (Author's abstract)

**EFFECT OF WATER QUALITY ON BACTER-
IOPLANKTON DENSITIES IN RIVER, BROOK
AND PEAT MINING WATER IN THE BASIN
OF THE HUMIC RIVER KIIMINKIJOKI,
NORTHERN FINLAND.**

Water and Environment District of Oulu (Finland).
K. Heikkinen, and A. Visuri.
Archiv fuer Hydrobiologie AHYBA4, Vol. 119, No. 2, p 215-230, 1990. 2 fig, 5 tab, 52 ref.

Descriptors: *Colloids, *Microorganisms, *Organic carbon, *Rivers, *Water pollution effects, Bacteria, Chemical properties, Finland, Humic substances, Iron, Phosphorus, Mining, Nitrogen, Peat, Peat bogs, Physical properties, Temperature effects, Water chemistry, Water temperature.

Total densities of suspended bacteria and physicochemical water quality parameters were studied in river, brook and peat mining water in the drainage basin of the humic Kiiminkijoki River in Finland. Bacterial densities ranged from 960,000 to 8,220,000 cells/ml, biomasses from 12 to 105 microgram C/L and cell volumes from 0.074 to 0.144 cu micrometers. Organic carbon in the bacterial biomasses accounted for 0.05-0.66% of total organic carbon concentrations, 0.51-5.47% of particulate organic carbon and 0.06-0.83% of dissolved organic carbon. Bacterial densities increased with water temperature. The results indicated that organic iron-phosphorus colloids were important for bacterial growth in these humic waters. Bacterial densities in the river also increased with increasing particulate organic carbon concentrations, but dissolved organic carbon alone had only a small influence on them. Microbial activity in the river was probably also limited by the low ammonium nitrogen concentrations. Bacterial growth in the peat mining water seemed largely to be controlled by detrital phosphorus content, and bacteria in bog iron-ore formation also seemed to be important. Concentrations of inorganic nitrogen, iron and phosphorus in filtrates and dissolved organic carbon, and also bacterial densities, increased in the river downstream of the peat production areas. The increased in bacterial densities in the area of loading was probably mainly due to increasing concentrations of inorganic nitrogen and organic iron-phosphorus colloids. The increase in inorganic nitrogen concentrations could mainly be attributed to loading from the peat mining areas. (Author's abstract)

**INFLUENCE OF SEASON AND EXERCISE ON
THE LETHAL TOXICITY OF CYANIDE TO
RAINBOW TROUT (SALMO GAIRDNERI).**

Concordia Univ., Loyola Campus, Montreal (Quebec). Ecotoxicology Research Lab.
S. M. McGeachy, and G. Leduc.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 3, p 313-318, May 1988. 2 fig, 4 tab, 27 ref.

Descriptors: *Cyanide, *Toxicity, *Trout, *Water pollution effects, Environmental effects, Exercise effects, Fish behavior, Seasonal variation.

The response of continuously exercised and non-exercised juvenile rainbow trout (Salmo gairdneri Richardson) to lethal levels (96-hour LC50) of cyanide was examined for different seasons of the year. Trout were acclimated to the 12 C test temperature for 3-4 weeks, under a 12 hour photoperiod before being tested at different times of the year. In summer, there was no significant difference of sensitivity between exercised and non-exercised trout. From summer to winter, the 96-hour LC50 for exercised trout remained unchanged at 0.052 mg/L cyanide, while the LC50 of the non-exercised trout dropped significantly to 0.043 mg cyanide/L. The median survival times of the two groups of trout were the same in the summer, but in winter the exercised fish survived twice as long as the non-exercised fish. A longer acclimation period of the non-exercised trout from 4 weeks to 10 weeks during the winter increased resistance to cyanide. (Author's abstract)

**HISTOPATHOLOGY OF RAINBOW TROUT
EXPOSED TO A BLEACHED KRAFT PULP
MILL EFFLUENT.**

Montreal Univ. (Quebec). Dept. of Occupational and Environmental Health.
C. M. Couillard, R. A. Berman, and J. C. Panisset.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 3, p 319-323, May 1988. 1 fig, 5 tab, 18 ref.

Descriptors: *Fish, *Histology, *Pulp wastes, *Toxicity, *Trout, *Water pollution effects, Bacteria, Environmental effects, Fins, Fish diseases, Gills, Water pollution.

The toxicity of an untreated bleached kraft pulp mill effluent was evaluated histopathologically, using rainbow trout. Gills, liver, kidney, spleen, digestive tract, and skin were examined in a 96-hour LC50 acute test. Fish exposed to lethal concentrations of effluent had an extensive fusion of gill lamellae. This lesion was also present in fish that survived the 96-hour LC50 acute test but to a lesser extent. Trout exposed for 20, 40, and 60 days to sublethal effluent concentrations were also examined. No lesions that could be attributed specifically to the effluent were observed, but exposed fish had a higher incidence of fin necrosis and damaged gills than the unexposed fish after 40 and 60 days. Loss of resistance to bacterial pathogens may be a significant stress-related effect of this effluent in fish exposed for long periods to low concentrations. (Author's abstract)

TOXICITY TESTING OF SUBLETHAL EFFECTS OF DREDGED MATERIALS.
Old Dominion Univ., Norfolk, VA. Applied Marine Research Lab.
R. W. Alden, A. J. Butt, and R. J. Young.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 3, p 381-389, May 1988. 7 fig, 1 tab, 24 ref. U.S. Army Corps of Engineers contract number DACW65-81-C-0051.

Descriptors: *Dredging wastes, *Hampton Roads, *River sediments, *Shrimp, *Toxicity, *Water pollution effects, *Water pollution sources, Dredging, Elizabeth River, Path of pollutants, Pollution load, Virginia, Water pollution.

A series of toxicity tests were conducted on liquid and suspended solid phase fractions of sediments from the Port of Hampton Roads, Virginia. There were significant sublethal effects associated with exposure of the test organisms to fractions of sediments taken from certain stations in the Port of Hampton Roads. The respiration rates of the grass shrimp populations were depressed dramatically upon exposure to the liquid and suspended solid fractions of sediments from the most highly industrialized region of the Southern Branch of the Elizabeth River. Likewise, he hyporegulation capacity of grass shrimp exposed to high salinities declined following exposure to the elutriates from the same stations. The low levels of mortalities was apparently due to the removal of the most highly contaminated sediments by maintenance dredging operations 4-6 months prior to the tests. Lethal effects of the sediments were observed to return during tests 18 months following dredging. The sublethal effects of the sediments appear to be negligible in a region of the Southern Branch where the River makes a right angle turn and the sediments are somewhat sandy. The stations further upstream produced moderate sublethal effects, but only low levels of mortalities. The relative quality of the sediments which would be dredged during any future harbor deepening operations appears to be quite good. The sublethal effects of sediments composited to a depth of 3m did not produce significant sublethal effects. The toxic agent(s) producing respiratory depression and diminishment of osmoregulation capacity is unknown, but previous investigations indicate that this type of sublethal response is not uncommon and may be produced by different types of pollutants. CHRONIC EFFECTS OF 2,2'-DICHLOROBIPHENYL ON REPRODUCTION, MORTALITY, GROWTH, AND RESPIRATION OF DAPHNIA PULICARIA.
Minnesota Univ., Minneapolis. Dept. of Ecology and Behavioral Biology.
S. D. Bridgham.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 6, p 731-740, November 1988. 7 fig, 4 tab, 28 ref. EPA Grant CR810775.

Descriptors: *Daphnia, *Polychlorinated biphenyls, *Sublethal effects, *Toxicity, *Water pollution effects, Biological studies, Environmental effects, Water pollution.

Previous studies have shown toxic effects of polychlorinated biphenyls (PCBs) on aquatic life only in the microgram/L range, well above normal ambient concentrations. Daphnia pulicaria was isolated from Lake Erie and exposed to 50 ng/L to 10 microgram/L of 2,2'-dichlorobiphenyl (DCB) in lifetable and physiological studies. Reproduction, mortality, growth, and respiration were measured for periods up to the entire lifespan of the animal with and without the use of an organic surfactant. One experiment was conducted for three generations of the daphnid continuously exposed to 2,2'-dichlorophenyl. Significant mortality and inhibition of reproduction were found at levels as low as 50-100 ng/L in lifetable studies, an no safe level could be determined. These are among the lowest levels ever reported for a PCB congener to cause significant biological effects. A unique, yet repeatable, dose-response curve occurred in lifetables with maximum inhibition at low to intermediate concentrations. Inhibition at the highest level tested, 10 microgram/L, occurred only after continuous exposure for three generations. Increasing concentrations of 2,2'-dichlorobiphenyl stimulated growth, while respiration experiments yielded variable results. (Author's abstract)

Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 6, p 789-797, November 1988. 2 fig, 5 tab, 21 ref.

Descriptors: *Fish diseases, *Pulp wastes, *Water pollution effects, Bleak, Environmental effects, Gulf of Bothnia, Perch, Sculpin, Sublethal effects, Sweden, Water pollution.

In 1980 and 1981, fourhorn sculpin, Myoxocephalus quadricornis, were sampled systematically in the Gulf of Bothnia (Sweden) to monitor skeletal deformation related to bleached kraft mill effluents. Elevated frequencies of deformation were found outside several industries and a thorough study at one industry verified a correlation between distance from the industry and incidence of spinal deformation. Current laboratory investigation with juvenile fourhorn sculpin, exposed for 4.5 months to four pulp mill effluents resulted in elevated frequencies of vertebral deformation. Vertebrae composition and mechanical strength were altered as a result of the treatment. The same parameters were also altered for bleak, Alburnus alburnus, exposed for 3.5 months to the same effluents. The response pattern was, however, different and no vertebral deformation could be confirmed by X-ray technique. A field survey on feral perch, Perca fluviatilis, sampled in the vicinity of two kraft pulp mills with and without bleaching, on the Swedish east coast (Gulf of Bothnia) gave results similar to those obtained for bleak. Depleted ascorbate stores with subsequent disturbance in collagen metabolism is suggested as a possible mode of action. (Mertz-PTT)

SUBCLINICAL EFFECTS OF GROUNDWATER CONTAMINANTS. II. ALTERATION OF REGIONAL BRAIN MONOAMINE NEUROTRANSMITTERS BY BENZENE IN CD-1 MICE.
Utah State Univ., Logan. Dept. of Biology.
G. C. Hsieh, R. D. R. Parker, and R. P. Sharma.
Archives of Environmental Contamination and Toxicology AECTCV, Vol. 17, No. 6, p 799-805, November 1988. 1 fig, 3 tab, 32 ref. U.S. Geological Survey grant no. G-1255-04.

Descriptors: *Benzene, *Toxicity, *Water pollution effects, Brain, Chromatography, Groundwater pollution, Health effects, Mice, Neurological effects, Sublethal effects, Water pollution.

Benzene, a common groundwater contaminant, possesses neurotoxic and behavioral effects. Male, adult CD-1 mice were continuously fed drinking water ad libitum containing 0, 31, 166 and 790 mg/L benzene for four weeks. Endogenous levels of the catecholamines norepinephrine and dopamine, the catecholamine metabolites 3-methoxy-4-hydroxymandelic acid, 3,4-dihydroxyphenylacetic acid and homovanillic acid, and the indoleamine serotonin and it metabolite 5-hydroxyindoleacetic acid, were measured by high-performance liquid chromatography in six discrete brain regions. In the hypothalamus, the brain region richest in norepinephrine, concentrations of norepinephrine increased by 40% when mice received doses at 31 mg/L; 58% with 166 mg/L; and 61% with 790 mg/L. Significant increases of norepinephrine were also observed in the medulla oblongata and cerebellum. Dopamine concentrations increased significantly in the hypothalamus and corpus striatum. Increases of catecholamine metabolites were seen in a number of brain regions: midbrain (3,4-dihydroxyphenylacetic acid), corpus striatum (homovanillic acid, 3-methoxy-4-hydroxymandelic acid, and 3,4-dihydroxyphenylacetic acid), cerebral cortex (3-methoxy-4-hydroxymandelic acid, and cerebellum (3-methoxy-4-hydroxymandelic acid). Benzene ingestion significantly increased serotonin concentrations in the hypothalamus, corpus striatum, midbrain, cerebral cortex and medulla oblongata. Concomitant with increases of serotonin, 5-hydroxyindoleacetic acid increased in corpus striatum, midbrain, cerebral cortex and medulla oblongata. The findings indicate that oral ingestion of benzene by mice induced both synthesis and catabolism of the monoamine neurotransmitters investigated. (Author's abstract)

ENVIRONMENTAL EPIDEMIOLOGY OF NON-HODGKIN'S LYMPHOMA IN EASTERN NEBRASKA.
Nebraska Univ., Omaha.
D. D. Weisenburger.
American Journal of Industrial Medicine AJIMD, Vol. 18, No. 3, p 303-305, 1990. 13 ref. Nebraska Department of Health Grant LB-506.

Descriptors: *Cancer, *Epidemiology, *Groundwater pollution, *Human diseases, *Pesticides, *Population exposure, *Water pollution effects, Agricultural chemicals, Atrazine, Carbamate pesticides, Drinking water, Halogenated pesticides, Herbicides, Histology, Nebraska, Nitrates, Non-Hodgkin's lymphoma, Organophosphorus pesticides, Phenoxy acid herbicides.

The incidence of non-Hodgkin's lymphoma (NHL) is increased in many counties in eastern Nebraska. Histologic analysis has revealed a twofold increase in the clinically aggressive, diffuse large cell subtype of NHL. To investigate the possible association between NHL and agricultural exposures, a population-based case-control study was conducted in eastern Nebraska in 1985. Telephone interviews were conducted with 201 men having histologically confirmed NHL and 725 controls. Among men, the use of the herbicide 2,4-D was associated with a 50% increased risk of NHL (OR 1.5, 95% CI 0.9, 2.4). Personal exposure to 2,4-D more than 20 days per year increased the risk threefold (OR 3.3, 95% CI 0.5, 22.1). Several classes of insecticides were also associated with increased risk: organophosphates (OR 1.9, 95% CI 1.1, 3.1), carbamates (OR 1.8, 95% CI 1.0, 3.2), and chlorinated hydrocarbons (OR 1.4, 95% CI 0.7, 2.3). As a result of intense agricultural use, extensive contamination of shallow groundwater by nitrate and atrazine has also occurred in eastern Nebraska. A twofold increase of NHL is present in counties with greater than 20% of the wells contaminated by nitrate (>10 ppm) and in counties with intense fertilizer use. These findings suggest that NHL in eastern Nebraska may be related to the use of pesticides and nitrogen fertilizers. (Author's abstract)

DRINKING WATER CONTAMINATION AND THE INCIDENCE OF LEUKEMIA: AN ECOLOGIC STUDY.
New Jersey State Dept. of Health, Trenton. Div. of Occupational and Environmental Health.
J. Fagliano, M. Berry, F. Bove, and T. Burke.
American Journal of Public Health AJHEA, Vol. 80, No. 10, p 1209-1212, October 1990. 1 fig, 1 tab, 31 ref.

escriptors: *Cancer, *Drinking water, *Epidemi-
ogy, *Population exposure, *Public health,
/olatile organic compounds, *Water pollution ef-
cts, Leukemia, New Jersey, Regression analysis,
richloroethylene, Water pollution.

n ecologic study was performed to examine the
lation between the incidence of leukemias and
e occurrence of volatile organic chemical (VOC)
ntamination of drinking water supplies within a
idy area comprising subpopulations differentially
posed to drinking water VOCs (trichloroethy-
ie and related solvents). Populations served by
mmunity water supplies were classified into ex-
sure categories according to VOC contamina-
n status based on 1984-85 sampling data. Leuke-
a incidence data (1979-1984) were collected
m a population-based cancer registry. For fe-
les, the standardized incidence ratio was elevat-
only in towns in the highest of three exposure
egories. No association was observed in males
any of the exposure categories. A Poisson re-
ssion analysis of the data, using finer exposure
ata, indicated an increased risk among females
h increasing level of contamination which ap-
ared to be distributed evenly across all age
ata. The rate ratio for females at the highest
osure stratum for total non-trihalomethane
OCs compared to the least exposed stratum was
8. The observed association appears to suggest
t drinking water contaminated with VOCs may
rease the incidence of leukemia among exposed
ales, but caution is advised in the interpretation
hese results because of the uncertainties inher-
in ecologic studies. (Author's abstract)

ough highly beneficial for dental health, low
centrations of fluoride in environmental waters
be toxic to several organisms. In an era of
htened public awareness about the environ-
t, this may lead city officials to withhold im-
enting water fluoridation for environmental
ons. A mass balance approach was used to
uate this perceived risk. Generally speaking,
idated water loss during use, dilution of
ge by rain and groundwater infiltrate, fluoride
val during secondary sewage treatment, and
sion dynamics at effluent outfall combine to
nate fluoridation-related environmental ef-
. In Montreal, water fluoridation would raise
ge aquatic fluoride levels in the waste water
e immediately below effluent outfall by only
0.09 mg/L. Downstream, these changes
d be only 0.02-0.05 mg/L at 1 km, and 0.01-
mg/L at 2 km below outfall. Overall river
ide concentrations theoretically would be
d by 0.001-0.002 mg/L, a value not measura-
y current analytical techniques. All resulting
ntrations would be well below those recom-
ed for environmental safety and would not
d natural levels found elsewhere in Quebec.
erature review did not reveal any examples of
cipal water fluoridation causing recommend-
nvironmental concentrations to be exceeded,
ugh excesses occurred in several cases of
e industrial water pollution. (Author's ab-

**KEMIA INCIDENCE AND RADIOACTIV-
IN DRINKING WATER IN 59 IOWA
NS.**
Univ., Oakdale. Coll. of Medicine.
L. Fuortes, L. A. McNutt, and C. Lynch.
American Journal of Public Health AJHEAA, Vol. 80, No. 10, p 1261-1262 October 1990. 2 tab, 7 ref.

Descriptors: *Cancer, *Drinking water, *Epidemiology, *Leukemia, *Population exposure, *Public health, *Radium radioisotopes, *Water pollution effects, Iowa, Radioactivity, Statistical analysis, Water pollution.

Fifty-nine towns in Iowa with single source drinking water were stratified on the basis of radium content in finished non-softened water to test the hypothesis of an association with total or acute myeloid leukemia. Fourteen towns had radium concentrations in drinking water exceeding the EPA safety limit of 5 pCi/L. A small increasing trend existed for total leukemia with increased radium content in drinking water that is in accordance with either the hypothesis of no effect or of a small effect. Future study of cancer incidence and radium concentration in drinking water in these and other communities is needed to clarify the risk of leukemia secondary to naturally occurring Ra-226. BREEDING BIOLOGY OF THE SPOTTED SALAMANDER AMBYSTOMA MACULATUM (SHAW) IN ACIDIC TEMPORARY PONDS AT CAPE COD, USA.
Cape Cod National Seashore, South Wellfleet, MA.
J. W. Portnoy.
Biological Conservation BICOBK, Vol. 53, No. 1, p 61-75, 1990. 1 fig, 3 tab, 32 ref.

Descriptors: *Acid rain effects, *Acidic water, *Cape Cod, *Ephemeral lakes, *Hatching, *Salamanders, *Spawning, *Water pollution effects, Biological studies, Hydrogen ion concentration, Lignin, Mortality, Organic acids, Survival, Tannins, Toxicity.

Many researchers have expressed concern that temporary ponds could be the most sensitive freshwater bodies to atmospheric acidification because of isolation from inorganic soil buffers and direct exposure to both acidic rainfall and unbuffered snowmelt. The many temporary woodland ponds on Cape Cod appear especially vulnerable to acidification because of the low buffering capacity of local soils, the natural acidity from surrounding coniferous forest, and the low pH (4.0 to 5.0) of local precipitation. The relationship between water chemistry and breeding success of spotted salamanders (Ambystoma maculatum (Shaw)) was examined in temporary woodland ponds on outer Cape Cod, MA in 1985 and 1986. Most pond waters were dilute (median conductivity = 57 micromhos/cm (1 micromhos/cm = 0.1 mS/m)), acidic (median pH = 4.82), and highly colored (median = 140 Pt-Co units). Most acidity was due to abundant organic acids. Salamander survival to hatching was over 80% at 8 of 12 ponds monitored. Complete mortality, preceded by gross abnormalities, was observed only among embryos in the most acidic spawning pond (pH 4.3 to 4.5) in both years. Embryo transfers between ponds and laboratory studies indicated that reduced survival was due to the interaction of low pH with high tannin-lignin concentration. The use of amphibian embryonic survival to indicate acid rain effects is complicated by multiple habitat parameters and should only be attempted in conjunction with long-term population monitoring. Since about 1975, the striped bass populations in the Sacramento Valley Delta (California) have experienced a sharp decline. Accompanying this decline is the striped bass die-off which may be linked to application of thiocarbamate herbicides such as the chemically persistent thiobencarb (Bolero). The in vitro S-oxygenation of thiobencarb (p-chlorobenzyl-N,N-diethylthiocarbamate) in the presence of hepatic microsomes from freshwater and seawater-adapted striped bass was investigated. Thiobencarb S-oxide was the principal metabolite and accounted for 98% of the total thiobencarb metabolized by striped bass liver microsomes. Studies on the biochemical mechanisms for striped bass hepatic S-oxygenation suggest that this reaction is catalyzed largely by the flavin-containing monooxygenase and to a lesser extent by cytochromes P-450. Following the short incubation period used, no thiobencarb sulfone was detected and no evidence was found for a contribution of cooxidation in the S-oxidation of thiobencarb. This conclusion was supported by studies with microsomes and purified mammalian monooxygenases which also metabolized thiobencarb without cooxidizing factors. Highly purified cytochrome P-450IIB-1 S oxygenated thiobencarb more efficiently than highly purified hog liver flavin-containing monooxygenase. Thiobencarb S-oxide and thiobencarb sulfone were efficient carbamylating agents and reacted with thiol and amine nucleophiles, whereas thiobencarb itself was relatively stable to trans-thiocarbamylation. Monooxygenase-catalyzed S-oxygenation of thiobencarb by striped bass liver microsomes may represent a bioactivation process which could explain the known toxicity of thiobencarb in fish. Predicting the consequences of atmospheric deposition and land-use changes such as conifer afforestation/harvesting, for acidic and acid sensitive systems, requires a thorough understanding of the interactions of major chemical, biological, and hydrological processes. Mathematical models depicting streamwater and lake water chemistry behavior are well established and have successfully depicted short-term event streamwater data and historical acidification patterns for lake water. Among the hydrochemical mechanisms depicted in these models, emphasis is placed on ion-exchange and weathering reactions. A summary of soilwater and streamwater data from acidic catchments in Wales, Scotland, and Norway is presented. It is concluded that insufficient detail has been established to describe quantitatively the ion-exchange and weathering processes in determining streamwater chemistry. Such a description is required before reliance can be placed on mathematical models describing short-term and long-term changes. The need for manipulative studies is highlighted, emphasis being placed on minimizing perturbation of the system from field conditions. An appeal is made for the use of a standardized method for determining the exchangeable cations. The studies provide overwhelming evidence showing the incorrectness of the commonly used modelling assumption that Al(OH)3 solubility determines inorganic aluminum levels in the soil and streams. The importance of simple mixing of soil and ground water, in explaining streamwater aluminum-hydrogen ion relationships, is emphasized. (Korn-PTT)

At the Svartberget Research Catchment in northern Sweden, stream pH had risen to 5.7 after a period of dry summer weather in 1987 before it dropped to below 4.4 during three ensuing storm events. To clarify the relationship between flow pathways and episodic acidity, the sources of storm runoff and its acidity in one of the catchment hillslopes were investigated. Hydrological considerations locate the origins of the runoff within the upper four decimeters of the soil in a swath some 50 m wide along the stream. Groundwater remained alkaline throughout the episodes. Increases in the total organic carbon content of runoff appeared to play a central role in the stream pH decline. The episode's acidity and distinctive chemical fingerprint originated in the runoff's passage through the organic-rich forest mor and/or streambank vegetation. Results from a column-leaching experiment supported this hypothesis. Such localized origins of runoff and especially of acidity may be of significance when calculating the rate at which acid episodes in other catchments respond to changes in acid deposition. A better understanding of the interaction between runoff and organic material is needed to determine whether the acidity at Svartberget is natural or if it had been affected by atmospheric inputs of anthropogenic origin. (Author's abstract)

In recent years sulfate concentrations in the fresh waters of southern Norway have declined, presumably owing to reduced atmospheric emissions of sulfur dioxide in Western Europe. There has also been a parallel decline in calcium and magnesium in fresh waters. An important question to be resolved is whether reduced base cation concentrations can be explained predominantly as a response only to declines in sulfate levels, or whether concurrent soil acidification also plays a role. To help clarify long-term trends in freshwater chemistry and potential soil acidification, an investigation, in which all major chemical species were considered, was conducted in the Birkenes catchment, southern Norway. Emphasis was placed on the choice of statistical tools and soil water data. For the period 1972-1987, a steady decline was observed for calcium (1.1-1.4 microeq/L/yr) and magnesium (0.6-0.8 microeq/L/yr) in streams at the Birkenes catchment. No similar significant trends were observed for other chemical species or for discharge over the whole record, but sulfate declined over the last two years of the study. The long-term deterioration of streamwater chemistry is ascribed to soil acidification in the catchment, which may offset the beneficial effects of reductions of anthropogenic sulfur deposition. Results from monitoring of soil solutions from 1984-1987 indicate that reductions of sulfate are accompanied by further reductions of base cations, but not of hydrogen ion and inorganic monomeric aluminum. OUTBREAK OF CAMPYLOBACTER ENTERITIS ASSOCIATED WITH A COMMUNITY WATER SUPPLY.
Centre Hospitalier Regional de la Beauce, Beauceville East (Quebec). Dept. de Sante Communautaire.
M. Alary, and D. Nadeau.
Canadian Journal of Public Health CJPEA4, Vol. 81, No. 4, p 268-271, 1990. 1 fig, 1 tab, 22 ref.

Descriptors: *Campylobacter, *Enteric bacteria, *Path of pollutants, *Potable water, *Public health, *Water pollution effects, Chlorination, Coliforms, Contamination, Water quality.

In June 1987, an outbreak of acute enteritis occurred over a period of two weeks in a small rural community where the potable water supply is unfiltered and unchlorinated. Campylobacter jejeuni was isolated from six patients. A case control study performed in a local fiberglass shop where workers drink a lot of water, showed an association between the occurrence of enteritis and the consumption of ten or more 8 ounce glasses of water per day (Odds ratio = 6, p = 0.04). The attack rate of enteritis was 23.2% (13/56) and a dose response relationship was also noted (p = 0.05). C. jejeuni was not recovered from the local water supply, which had temporarily been chlorinated the day before the samples were taken. However, samples taken just before the outbreak showed high coliform counts. This episode suggests that unprotected water systems may be contaminated by C. jejeuni. (Author's abstract)

Differences between freshwater and seawater-acclimated guppies (Lebistes reticulatus) in the accumulation and excretion of tri-n-butyltin chloride (Bu3SnCl) and trephenyltin chloride (Ph3SnCl) were studied. The bioconcentration factors (BCF) of Bu3SnCl and Ph3SnCl reached plateau values after 7 and 10 days of exposure, respectively, in both types of fish. The BCF values of both Bu3SnCl and Ph3SnCl (460 and 110) in the freshwater fish were about twice as high as those (240 and 530) in the seawater-acclimated fish. The excretion rate of Ph3SnCl from the seawater-acclimated fish (0.30/d) was about twice as rapid as that from the freshwater fish (0.13/d), but there was no difference between the fish in the rate for Bu3SnCl (0.35 and 0.32/d). These differences are probably due to the differences in the chemical properties and the physiological mechanisms employed by the fish for regulation of the osmotic pressure. (Author's abstract)

The acidity of the organic layer and the underlyi soils associated with most undisturbed forests pr vide edaphic conditions which are not conduci to autotrophic nitrification. The pattern of nitrog accumulation and retranslocation of nutrients living biomass may be severely altered by anthr pogenic activities such as deforestation; fertiliz tion of podzolic forest soils; and industries, tra portation vehicles, etc. inducing acid rain. T nitrous acid hypothesis could explain the triggeri effect of drought on forest decline. The first ra fall after summer drought revivifies nitrifiers a so gives rise to an acidification push with nit acid production. But also denitrifiers are rapi revivified in anaerobic microsites. During this c matic event, intermediate NO2(-) of nitrificati denitrification (as undissociated HNO2 speci would react drastically and without discriminati on dead and living organic matter, thus alteri roots and mycorrhizas, particularly in the dir vicinity of aggregates. UENCE OF WASTE WATERS FROM THE
OF VENICE AND THE HINTERLAND
THE EUTROPHICATION OF THE
ON.

Venice Univ. (Italy). Facolta di Chimica Industriale.
B. Pavoni, A. Sfriso, R. Donazzolo, and A. A. Orio.
Science of the Total Environment STENDL, Vol. 96, No. 3, p 235-252, August 1990. 4 fig, 2 tab, 19 ref.

Descriptors: *Eutrophication, *Italy, *Venice Lagoon, *Wastewater pollution, *Water pollution effects, Canals, Coliforms, Hydrogen ion concentration, Metropolitan water management, Nutrients, Oxidation-reduction potential, Salinity, Sewer systems, Wastewater facilities.

The unique location of Venice, Italy, built on a number of islands in the middle of a lagoon, has rendered it impossible, up to now, to construct an adequate sewage system. Most of the industrial and urban wastewaters from the hinterland are conveyed to treatment plants which have been progressively enlarged and improved; wastewaters from the city are discharged directly into the lagoon. Four seasonal samplings of lagoon waters were carried out during successive phases of high and low tide at stations located within Venice and its surroundings to monitor various physico-chemical parameters (pH, redox potential, temperature), salinity, nutrient concentrations (nitrogen, phosphorus, carbon compounds) and bacteria (total coliform bacteria). Salinity was used as a parameter for estimating the hydrographic distance from the Adriatic Sea, and for grouping stations into five homogeneous areas. A negative correlation was found between salinity and the concentrations of nutrients. Gradients of increasing concentrations of nutrients were observed at increasing hydrographic distance from the sea. The contributions to eutrophication of fresh waters entering the lagoon from the hinterland and of wastewaters from the city have been estimated and found to be comparable. Some necessary interventions for the restoration of the lagoon are: increasing the efficiency of the treatment plants; diverting the canal courses from the hinterland into closed ponds suitable for cultivatable of aquatic plants; enlarging and deepening the natural lagoon channels; and opening one or more small dam-regulated canals. Meanwhile, an adequate sewage system for the city of Venice has to be designed and built. (Author's abstract)

HYDROGEOLOGIC ASSESSMENT OF EXPOSURE TO SOLVENT-CONTAMINATED DRINKING WATER: PREGNANCY OUTCOMES IN RELATION TO EXPOSURE.
California Univ., San Francisco. Dept. of Epidemiology and Biostatistics.
M. Wrensch, S. Swan, P. J. Murphy, J. Lipscomb, and K. Claxton.
Archives of Environmental Health AEHLAU, Vol. 45, No. 4, p 210-216, July/August 1990 2 fig, 4 tab, 11 ref.

Descriptors: *California, *Drinking water, *Groundwater pollution, *Statistical analysis, *Teratogenic effects, *Toxic wastes, *Water pollution effects, *Water pollution sources, *Well water, Flow models, Leakage, Toxicity, Trichloroethane.

The California Department of Health Services conducted several studies to investigate community concerns that an alleged cluster of adverse pregnancy outcomes might result from exposure to drinking water from a single well that was contaminated by trichloroethane and traces of other chemicals leaked from an underground storage tank of a semiconductor manufacturing firm in the Los Paseos neighborhood of Santa Clara County, California. Earlier studies in 1980 and 1981 found statistically significant excesses of spontaneous abortions and birth defects in a presumably exposed area compared with an unexposed area. This second interview study in 1986 was conducted to obtain information about the occurrence of these adverse pregnancy outcomes in an adjacent census tract that was presumed to have water exposure comparable to the originally studied area and to determine the occurrence of these outcomes in the original and new study areas after the contaminated well was closed in December 1981. Using quantitative methods to model movement of the solvent leak plume and water flow within the distribution system, it was estimated that women with adverse outcomes were no more likely to have received contaminated water than women with normal live births. The validity of this conclusion depends on the assumption that the two areas had comparable exposure. These results strengthen the hypothesis that exposure to water from the contaminated well were not responsible for the excess of adverse outcomes observed in the Los Paseos area. (Medina-PTT)

IMPACT OF DISTILLERY EFFLUENT APPLICATION TO LAND ON SOIL MICROFLORA.
National Environmental Engineering Research Inst., Nagpur (India).
A. Juwarkar, and S. A. Dutta.
Environmental Monitoring and Assessment EMASDH, Vol. 15, No. 2, p 201-210, September 1990. 5 fig, 3 tab, 12 ref.

Descriptors: *Bioindicators, *Industrial wastes, *Microorganisms, *Toxic wastes, *Wastewater utilization, *Water pollution effects, Actinomyces, Effluents, Nitrogen fixing bacteria, Rhizobium, Soil bacteria, Soil fungi.

A pot culture experiment was conducted to evaluate the effect of different treatments of distillery wastewater mixed with domestic waste stabilization pond effluent (1:1) on populations of bacteria, fungi, actinomycetes, nitrogen fixing bacteria, and on the nodulation of groundnut plants. The results indicated that raw wastewater decreased the population of bacteria, fungi and actinomycetes. The growth rates of Rhizobium and Azotobacter were also reduced after raw wastewater application. The toxic effect of raw wastewater was minimized when it was mixed with stabilization pond effluent (1:1). This was demonstrated by an increase in the population of all microorganisms studied. When groundnut plant was irrigated with raw distillery wastewater, no fruits were produced and there was also less nodulation. Raw distillery water is therefore very toxic to soil microorganisms which are important in the soil ecosystem. (Author's abstract)

Descriptors: *Aluminum sulfate, *Drinking water, *Water pollution, *Water pollution effects, Bioaccumulation, Human physiology, Water pollution sources.

Two healthy individuals who drank water accidentally contaminated at source with aluminum sulfate were investigated 6-7 months later. On July 6, 1988, at the Lowermoor water treatment works near Camelford, Cornwall, England, 20 tonnes of 8% aluminum sulfate solution were inadvertently deposited directly into a water tank (contact tank) instead of the storage tank. Because the contact tank was downstream from the pH monitors at the treatment works, the contaminated water was distributed. Shortly afterwards some of the 20,000 potential consumers noticed that the water had an unpleasant metallic taste and some manifested various symptoms. Water Al concentrations recorded at the time of the contamination ranged from 30 to 620 mg/L, levels that are well above the maximum admissable concentration of 0.2 mg/L given in the

EC Drinking Water Directive. The two individuals examined, claimed to have drunk the water at the time it was most heavily contaminated and the early symptoms of ulceration of the lip and mouth accord with mucosal damage resulting from the ingestion of an acidic, metallic solution. The bone biopsy findings of local areas of aluminum staining indicate a short period of increased gastrointestinal absorption of aluminum. During the pollution incident the aluminum was presumably in an abnormally acidic medium so absorption was facilitated. Aluminum absorption is also enhanced when the integrity of the intestinal mucosa is interrupted. These findings show that under certain conditions, normal individuals can absorb aluminum via the gut, and that such aluminum can be deposited in bone. (Author's abstract)

HEALTH EFFECTS OF CHEMICAL WASTE IN AN URBAN COMMUNITY.
Queensland Univ., Brisbane (Australia). Dept. of Psychiatry.
M. P. Dunne, P. Burnett, J. Lawton, and B. Raphael.
Medical Journal of Australia MJAUAJ, Vol. 152, No. 11, p 592-597, 1990. 6 tab, 27 ref.

Descriptors: *Australia, *Chemical wastes, *Hazardous wastes, *Public health, *Urban areas, *Water pollution effects, Human diseases, Morbidity, Mortality, Stress, Surveys, Toxicity.

Results are given of a community health survey of people living near a hazardous chemical waste site in Kingston, Queensland, Australia. Compared with a matched control group, people near the site were no more likely to report serious diseases. Likewise, reports of cancer and mortality rates did not differ in the two groups. Kingston residents reported higher rates of symptoms of general poor health, high levels of stress and anxiety, and a higher incidence of miscarriages. The reports of poor physical health appeared to be independent of proximity to the hazardous waste site and duration of residence in the area. Symptom prevalence and perceived recent decline in health correlate most strongly with the stress and anxiety measures. While long-term investigation is necessary, it appears at this stage that the chemical waste is not associated with an increase in major diseases as reported by those who were interviewed. Healthwise, it is clear that the situation has had a negative impact. (Author's abstract)

BIODEGRADABILITY OF MONO- AND DISUBSTITUTED BENZENE-DERIVATIVES (ZUR BIOLOGISCHEN ABBAUBARKEIT MONO- UND DISUBSTITUIERTER BENZOLDERIVATE).
Hoechst A.G., Frankfurt am Main (Germany, F.R.).
H. Wellens.
Zeitschrift fuer Wasser - und Abwasser Forschung ZWABAQ, Vol. 23, No. 3, p 85-98, June 1990. 3 fig, 4 tab, 57 ref. English summary.

Descriptors: *Aromatic compounds, *Benzene, *Biodegradation, *Wastewater treatment, Analytical techniques, Decomposition, Degradation, Zahn-Wellens test.

The biodegradability of 161 mono-, and disubstituted benzene derivatives was determined using the static Zahn-Wellens test and compared with the results from other laboratories. The qualification of the test method is discussed as well as the valuation of the results following the course of testing. All of the monosubstituted compounds with only one exception, proved to be biodegradable. The dependence of the biodegradability of the disubstituted benzene derivatives, as a function of type and position of the substituents, is discussed. From 141 compounds tested, 21 proved to be resistent against decomposition, while 32 derivatives exhibited prolonged acclimatization or degradation times. (Author's abstract)

Descriptors: *Anaerobic digestion, *Biological wastewater treatment, *Fluidized bed process, Biological treatment, Chemical oxygen demand, Protozoa, Retention time, Temperature, Wastewater treatment.

Two anaerobic fluidized beds were tested with lab-scale equipment using synthetic wastewater. The experiments were designed to examine the effect of reduced temperatures in the fluidized bed (14 C and 18 C), low influent substrate concentration (mean soluble COD 405 mg/l; 30-580 mg/ SCOD) and short retention times (2.0 and 5.8 hours) on the efficiency of the anaerobic process. About 20-25% SCOD-reduction could be achieved at both temperatures and at organic loading rates as high as 0.12-0.86 kg/ cu m COD/d. The variability of the individual numbers of Histomonas meleagridis (SMITH) was observed. This flagellate was the only protozoan living in the two anaerobic fluidized beds. (Author's abstract)

SIMPLIFIED OPTIMISATION PROCEDURE FOR FIXED BED ADSORPTION SYSTEMS.
Queen's Univ., Belfast (Northern Ireland). Dept. of Chemical Engineering.
G. McKay, and M. J. Bino.
Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 33-41, May 1990. 10 fig, 4 ref.

Descriptors: *Adsorption, *Design criteria, *Fixed bed adsorption, *Optimization, *Systems analysis, *Wastewater treatment, Activated carbon, Flow rates, Liquid retention, Mercury, Phenols.

Selection of contacting and regeneration systems for granular activated carbon utilization in wastewater treatment processes is integrated. The operating line concept can be used to optimize a basic bed design to achieve the lowest cost. Once the operating line has been established, it is possible to select the combination of carbon exhaustion rate and liquid retention time which give the optimum or lowest-cost design. For a given system, in which liquid flow rate, impurity concentrations and carbon characteristics are fixed, the costs are dependent upon two primary variables: the carbon exhaustion rate, and the superficial liquid retention time. These two variables were determined for phenol, p-chlorophenol, and mercuric ions onto activated carbon in fixed bed systems. The effects of secondary process variables such as flow rate and the effect of percentage breakthrough show that for flow rates below 3.3 cu m/sec there is no significant gain in the carbon exhaustion rate by reducing the flow rate. When the flow rate is increased from 2.5 to 3.33 cu m/sec, the increase in carbon exhaustion rate is about 20%. The results have been used to predict optimum conditions for the systems based upon the C exhaustion rate and the empty bed residence time (EBRT). For a fixed EBRT, the carbon exhaustion rate is higher for lower percentage breakthrough required. For a fixed operating condition such as flow rate and pollutant initial concentration, the carbon usage rate reaches an optimum higher value corresponding to a minimum EBRT. (Brunone-PTT)

LABORATORY MESOCOSM STUDIES OF FE, AL, MN, CA, AND MG DYNAMICS IN WETLANDS EXPOSED TO SYNTHETIC ACID COAL MINE DRAINAGE.
Villanova Univ., PA. Dept. of Biology.
R. K. Wieder, M. N. Linton, and K. P. Heston.
Water, Air and Soil Pollution WAPLAC, Vol. 51 No. 1/2, p 181-196, May 1990. 5 fig, 1 tab, 31 ref

Descriptors: *Acid mine drainage, *Artificial wet lands, *Mesocosms, *Wastewater treatment, *Wet lands treatment, Aluminum, Calcium, Cost analysis, Iron, Magnesium, Manganese, Mine wastes Peat, Trace metals.

To evaluate the potential for constructed wetland to treat acid coal mine drainage, six model wetlan mesocosms (each 2.4 m by 15 cm) were filled wit Sphagnum peat (15 cm deep), planted either wit cattails (Typha latifolia) and living Sphagnum living Sphagnum only, or left as bare peat (mesocosms per treatment). The model wetland were exposed to synthetic acid coal mine drainag (pH 3.5, concentrations of iron, aluminum, manga nese, calcium and magnesium ions of 78.8, 10.0 5.2, 12.0 and 4.5 mg/L, respectively) at a rate of 9 ml/min, 6 hours/day, 5 days/week over a 16 wee period. Chemical analyses of peat at periodic inter vals indicated that the model wetlands were n sources of aluminum, manganese, calcium, an magnesium, but net sinks for iron. Type of vegeta tion had no significant effect on iron retention; c the 204 g of iron added to the model wetlan systems, 162 g were retained. Formation of iro oxides accounted for 73 to 86% of the iron reten tion, with exchangeable iron contributing 0.2 t 1.2%, organically bound iron contributing 4 t 19%, and residual iron contributing 7 to 15% c total iron retention. Iron retention was greatest the inflow ends of the model wetlands where iro retention appeared to reach saturation at a fin iron concentration in the peat of 235 mg/g. At th rate of application of the synthetic acid mine drai age, the model wetland systems would hav reached an estimated complete iron saturation aft 157 days. The mesocosm approach could be usef in generating site-specific data that can be applie to the formulation of cost-benefit analyses that ca compare a proposed wetland treatment syste with alternative conventional chemical metho for treating acid mine drainage. Monitoring of thermophilic campylobacters in tw Libyan sewage treatment plants has shown that t communities of Tripoli and Sabratha almost c tainly harbor campylobacters capable of produci enteritis. The most probable number of thermop lic campylobacters per 100 ml ranged betwe 3733 and 6277 in the primary sedimentation tan at the two sewage treatment plants. The plant Tripoli eradicated the campylobacters from eff ent by secondary treatment with trickling filtrati followed by chlorination. The plant at Sabrat which was not working well at the time of sa pling, reduced campylobacter numbers by o 53% and 74% during secondary treatment in stabilization pond. A reservoir in Sabratha, whi received effluent from the stabilization pond a which supplies water for irrigation, also contain thermophilic campylobacters. In both treatm plants, campylobacters were eradicated fr sewage sludge by digestion and drying. (Autho abstract)

SELECTIVE ADSORPTION OF ARSENIC(V) ION BY USE OF IRON(III) HYDROXIDE-LOADED CORAL LIMESTONE.
Kagoshima Univ. (Japan). Dept. of Applied Chemistry.
S. Maeda, A. Ohki, Y. Tsurusaki, and T. Takeshita.
Separation Science and Technology SSTEDS, Vol. 25, No. 5, p 547-555, April 1990. 6 fig, 1 tab, 8 ref.

Descriptors: *Adsorption, *Arsenic, *Chemical treatment, *Limestone, *Wastewater treatment, Adsorption-desorption, Anions, Corals, Hydrogen ion concentration, Industrial wastewater, Iron, Phosphates.

In Japan, the arsenic level of water is regulated below 0.5 ppm in wastewater and 0.05 ppm in natural water. Accordingly, a treatment process is necessary to remove arsenic from industrial wastes in order to reduce its arsenic content below regulated values. By use of iron(III) hydroxide-loaded coral limestone (Fe-coral) as an adsorbent, a trace level of arsenic(V) ion in aqueous solution could be efficiently and selectively adsorbed onto the adsorbent surface. The arsenic adsorptibility of the Fe-coral depended upon the amount of iron(III) hydroxide loaded on the coral limestone. The arsenic adsorption was almost unaffected by the initial pH of the solution in the pH range 2-10, and was not practically influenced by the addition of such anions as chloride, nitrate, sulfate, perchlorate, and acetate in the aqueous solution. However, only coexisting phosphate caused a great depression in the arsenic adsorption. The arsenic adsorbed onto Fe-coral was only slightly desorbed in contact with aqueous solution under a wide pH range (3.5-10). The arsenic adsorption was effectively applied to a column-type operation. (Author's abstract)

HEAVY METAL DISTRIBUTION IN ANAEROBIC SLUDGES.
Universidad Complutense de Madrid (Spain). Dept. de Ingenieria Quimica.
J. Tijero, E. Guardiola, M. Cortijo, and A. Diaz-Barrionuevo.
Separation Science and Technology SSTEDS, Vol. 25, No. 5, p 653-658, April 1990. 1 fig, 1 ref, 9 ref.

Descriptors: *Anaerobic digestion, *Digested sludge, *Heavy metals, *Sludge analysis, Wastewater treatment, Chemical analysis, Chemical composition, Copper, Effluents, Nickel, Sludge solids, Zinc.

The distribution of the heavy metals Cu, Ni and Zn in the different phases of the effluent proceeding from an anaerobic digester operating under complete mixture conditions was studied. Specifically, the heavy metal distribution between the solid sludge and supernatant liquid of the final effluent was measured. Cu retention was very high, 96-98%, and increases as the concentration in the effluent increases. An increase in Ni concentration in the effluent produces a decrease in the retai associated with the solid effluent, going from 98% for 5 mg/L to 81% for 30 mg/L. Some 90% of the Zn was retained in the solid sludges. Thus, small amounts of heavy metals remain in the clear liquid of the effluent. (Author's abstract)

SOLVENT SUBLATION OF HEXACHLOROBUTADIENE AND 2,4,6-TRICHLOROPHENOL.
National Tsing Hua Univ., Hsinchu (Taiwan). Dept. of Chemistry.
C. Y. Shih, W. D. Han, and S. D. Huang.
Separation Science and Technology SSTEDS, Vol. 25, No. 4, p 477-487, April 1990. 4 fig, 6 tab, 20 ref.

Descriptors: *Chlorinated hydrocarbons, *Separation techniques, *Solvent sublation, *Solvents, *Wastewater treatment, *Water analysis, *Water treatment, Air-water interfaces, Organic solvents, Surfactants, Volatile organic compounds.

Solvent sublation, a surface chemical separation method, has shown promise for the removal of certain types of organic compounds from aqueous systems. In the solvent sublation procedure, a surface-active (or volatile) solute is transported from the aqueous phase to an overlying layer of nonvolatile organic liquid on the air-water interfaces (or in the interior) of bubbles rising through the solvent sublation column. Hexachlorobutadiene (HCB) and 2,4,6-trichlorophenol were removed from aqueous solutions into paraffin oil by solvent sublation. Over 99% of HCB was removed from a solution containing 100 ppb HCB initially in 10 min. The rate of removal of HCB by air stripping is somewhat slower than that by solvent sublation. The effects of added salt and ethanol on solvent sublation and air stripping of HCB were studied. About 64% of 2,4,6-trichlorophenol (TCP) were removed by solvent sublation from a solution containing 50 ppm 2,4,6-trichlorophenol initially at pH 1.84 for a 1 hour run. The rate of removal of 2,4,6-trichlorophenol can be improved by adding the cationic surfactant, hexadecyltrimethylammonium bromide (HTA). As high as 95% of 2,4,6-trichlorophenol was removed in 1 hour if 10 ppm HTA was added to the solution before solvent sublation runs. (Hoskin-PTT)

HAZARDOUS WASTE MINIMIZATION: SOURCE REDUCTION ALTERNATIVES IN THE AEROSPACE INDUSTRY.
CH2M Hill, Milwaukee, WI.
H. G. Allerton.
Journal of Environmental Health JEVHAH, Vol. 53, No. 1, p 28-29, July/August 1990. 1 tab, 3 ref.

Descriptors: *Aerospace industry, *Hazardous waste disposal, *Hazardous wastes, *Industrial wastes, *Waste recovery, *Waste reduction, *Waste treatment, Cyanide, Halogenated wastes, Heavy metals, Solvents, Waste identification, Waste minimization.

Aerospace industry research and manufacturing operations generate a diverse spectrum of chemical wastes. A cooperative effort by three major aerospace companies and the California Department of Health Services successfully identified alternatives for hazardous waste minimization. A priority was given to source reduction alternatives that would allow the generator to cost-effectively maximize on-site activity to reduce liabilities associated with off-site waste disposal. Study coordinators developed a standard data reporting form to collect hazardous waste generation and disposal information from a majority of the three companies' research and manufacturing operations located in southern California. Waste streams were then correlated with the processes or activities responsible for generating the wastes. Candidate waste streams were evaluated with respect to on-site treatment methods that have either been applied in other industries or have recently become commercially available. Available off-site treatment methods were identified and summarized for commercial treatment, storage and disposal facilities that carry out recycling, destruction or treatment of the types of waste streams covered in the study. The following water stream categories were targeted for potential waste minimization: spent halogenated solvents, ferric chloride solutions, photodeveloping solutions, water soluble coolants and cutting oils, cyanide plating solutions, heavy metal waste treatment sludges, noncyanide plating/etching/stripping solutions, plating in cleaning solutions, and lab pack miscellaneous wastes. These waste streams, typical of the aerospace industries' operations, represent more than 90% of the total volume of hazardous waste generated by the participant companies. (Mertz-PTT)

WASTEWATER TREATMENT, THE UTILIZATION OF EARTH MATERIALS AS COAGULANTS.
Cleveland State Univ., OH. Dept. of Geological Sciences.
H. H. Lo, and Y. T. Hung.
Journal of Environmental Health JEVHAH, Vol. 53, No. 2, p 22-25, September/October 1990. 8 fig, 6 ref.

Descriptors: *Coagulation, *Materials testing, *Municipal wastewater, *Wastewater treatment, Activated carbon, Basalts, Carbon, Granites, Limestone, Organic carbon, Pretreatment of wastewater, Raw wastewater, Shales, Turbidity, Wastewater, Zeolites.

Removal of total organic carbon and total suspended solids are major concerns in municipal wastewater treatment. The effects of several earth materials, at varying dosages, were investigated as potential coagulants and compared to activated carbon and fly ash. Wastewater samples were collected from the city of Painesville Pollution Control Plant in Painesville, OH and from the Central Wastewater Treatment Plant in Solon, OH. Earth materials used for coagulation study were granite, basalt, shale, limestone and zeolite. Dosages used were 0.4, 1.0, 2.0, 4.0, and 6.0 g/L. For each of the coagulants tested, total organic carbon concentrations were lower in wastewaters containing coagulants than in the untreated wastewater, and the difference was more pronounced in the primary wastewater samples. Limestone was most efficient for primary effluent, while granite worked best for secondary effluent. Zeolite was most effective in removing sodium, calcium, and magnesium. Use of earth materials in the coagulation of municipal wastewaters at various degrees of pretreatment also increased the turbidity of wastewater. Powdered activated carbon effectively removed turbidity in the raw wastewaters and primary effluent, as well as effectively removing total organic carbon from wastewaters. (Mertz-PTT)

INNOVATIVE SLUDGE DRYING BED DESIGN.
Camp, Dresser and McKee, Inc., Bradenton, FL.
J. A. Banks, and W. K. Lederman.
Public Works PUWOAH, Vol. 121, No. 10, p 112, 134, September 1990. 1 fig.

Descriptors: *Sand filters, *Sludge drying, *Sludge filters, *Wastewater treatment, *Wastewater treatment facilities, Cellular confinement system, Florida, Gravity filters, Percolating filters, Sludge.

Dewatering sludge at wastewater treatment plants has traditionally been a major operational concern. Smaller facilities rely on the sand filter drying bed for sludge dewatering. The sludge is applied to a graduated sand/gravel media. The water separates from the solids in the sludge via gravity and percolates down through the media. The sand filter's upper layers are of a finer material to filter out the solid particles of the liquid sludge. Removing dried sludge from sand filter drying beds can be a problem because small tractors or loaders cannot operate on the loose soils of a conventional sand drying bed. Because of this, past methods used to clean the beds have included hand labor and various forms of mechanical devices that are not directly supported by the sand structure. In Florida, the Sarasota County-Solid Waste Operations Division had a problem with its fixed-mechanical, vacuum sludge-drying beds, which were used to dewater a chemically oxidized septage sludge. The fixed media material deteriorated under constant use and replacement was very expensive. A product, known as the cellular confinement system, had been developed specifically to support vehicular traffic over poor soil conditions. In September 1989, a cellular confinement system was installed in the top sand layer in one of the two sand filter drying beds at the Sarasota facility. Since installing the cellular confinement system, no change was noticed in the filter bed's drying efficiency compared to it other bed without the cellular confinement system. Clean-up operations have been extensively improved, even beyond that of the original

fixed-media filter bed. In April 1990, the waste operations division converted its second fixed-media filter bed to a sand filter bed reinforced with the cellular confinement system to further increase the efficiency of its operation. Through this system, maintenance costs have been cut by 50%. (Mertz-PTT)

SURVEY OF SMALL SEWAGE TREATMENT FACILITIES IN OHIO.
Ohio State Univ., Columbus. Dept. of Agricultural Engineering.
K. Mancl.
Ohio Journal of Science OJSCA9, Vol. 90, No. 4, p 112-117, September 1990. 9 fig, 11 ref, append.

Descriptors: *Ohio, *Surveys, *Wastewater facilities, *Wastewater management, *Wastewater treatment, Aerobic treatment, Data acquisition, Permits, Site selection, Urban areas.

In 1987, a small sewage treatment facilities survey was conducted of all county and local health departments in Ohio. The objective was to learn how local sewage treatment facilities programs are managed, the types of systems in use, the numbers of permits issued, and the number of systems that are failing. Survey results indicate that urban areas in Ohio have the largest health departments and account for the largest number of permits issued, with over 13,000 permits issued in 1986. Site evaluation procedures varied greatly across the state. In 25 counties, permits were issued without a visit to the site. Sanitarians estimated that 27% of the septic systems are failing. Aerobic systems are used heavily in Ohio, while alternative systems have limited use. To address the problems of failing systems and unsuitable sites for septic systems, more information is needed at the county level about alternative sewage systems and on-site system management. Research Journal of the Water Pollution Control Federation JWPFA5, Vol. 62, No. 6, p 763-770, September/October 1990. 1 fig, 5 tab, 40 ref. EPA Grants R-804749 and R-806307, and EPA Contract 68-03-1706.

Descriptors: *Killifish, *Marine animals, *Mortality, *Municipal wastewater, *Shrimp, *Wastewater treatment, *Water pollution control, *Water pollution effects, Activated sludge, Chlorination, Flocculation, Florida, Population exposure, Primary wastewater, Secondary wastewater treatment, Toxicity, Wastewater dilution.

The effects of treatment and seawater dilution of municipal wastewater on marine organisms were determined at an experimental facility in southeast Florida that provided both unchlorinated and chlorinated effluent from three standard treatments: primary settling, chemical flocculation, and activated sludge secondary treatment. Exposure tests lasting longer than one month were conducted on the sheepshead minnow (Cyprinodon variegatus) and the pink shrimp (Penaeus duorarum), with each of these six effluent types at seawater dilution ratios of 30:1, 100:1, and 300:1. The shrimp showed a much more sensitive response than the minnow. Almost 100% mortality occurred for shrimp exposed to the unchlorinated 30:1 seawater dilutions of primary-settled wastewater, while mortality for the other two effluents was similar to that of controls. Mortality could not be attributed to any of the chemicals measured in the wastewater. For the 30:1 dilution experiments, chlorination usually resulted in much higher toxicity; increasing the dilution factor from 30:1 to 100:1 reduced the mortality observed (in both chlorinated and unchlorinated samples) essentially to control levels. Little bioaccumulation of metals or chlorinated organics was observed in exposed specimens. (Author's abstract)

INTERACTION BETWEEN SULFATE REDUCERS AND METHANOGENS FED ACETATE AND PROPIONATE.
Iowa Univ., Iowa City. Dept. of Civil and Environmental Engineering.
G. F. Parkin, N. A. Lynch, W. C. Kuo, E. L. Van Keuren, and S. K. Bhattacharya.
Research Journal of the Water Pollution Control Federation JWPFA5, Vol. 62, No. 6, p 780-788, September/October 1990. 7 fig, 5 tab, 27 ref. U.S. EPA Contract R-811657-01-0.

Descriptors: *Acetates, *Anaerobic digestion, *Methane bacteria, *Propionate, *Sulfates, *Sulfur bacteria, *Wastewater treatment, Anaerobic bacteria, Biological treatment, Biological wastewater treatment, Chemostats, Organic loading, Sulfides.

Anaerobic chemostats maintained at solids retention times of 15, 25, and 40 days were used to investigate the interaction between sulfate-reducing bacteria (SRB) and methane bacteria fed acetate and propionate. Organic loading rates of 0.25-0.50 g COD/L-d were used with feed COD/S ratios ranging from 60/1 to 2/1. Results indicated that SRB play an unexpected role in process failure. When systems failed, both sulfate reduction and methane production shut down. Levels of hydrogen sulfide associated with irreversible failure were near 60 mg S/L for both acetate and propionate systems; corresponding total dissolved sulfide levels were 145 mg S/L for acetate systems and nearly 200 mg S/L for propionate systems. For similar loading conditions, propionate systems failed sooner than acetate systems. For the conditions tested, solids retention time had little impact on overall process performance and metal nutrition was not a problem. The maximum tolerable sulfate loading rates were estimated to be 26 and 33.3 mg S/L-d for the propionate and acetate systems, respectively. (Author's abstract)

DENITRIFICATION BY AN EXPANDED BED BIOFILM REACTOR.
D. V. MacDonald.
Research Journal of the Water Pollution Control Federation JWPFA5, Vol. 62, No. 6, p 796-802, September/October 1990. 9 fig, 6 tab, 9 ref.

Descriptors: *Biofilm reactors, *Denitrification, *Wastewater reactors, *Wastewater treatment, Anoxic conditions, California, Methanol, Nitrates, Nitrogen, Rancho California Wastewater Reclamation, Wastewater facilities, Wastewater renovation.

The Rancho California Wastewater Reclamation Plant, which has a design capacity of 23.6 mL/d, is located in Southern California approximately 64 km northeast of the city of San Diego. The effluent from this plant is used for irrigation and groundwater recharge. In order to protect the local groundwater from nitrite contamination, the plant must nitrify and subsequently denitrify the plant's effluent to a nitrate-N concentration of 2.5 mg/L. The influent nitrate-N concentration to the denitrification facility is normally in the range of 15 to 20 mg/L. Denitrification is achieved with an upflow expanded bed biofilm reactor. The reactor is designed for a loading of 3.0 kg of nitrate-N/day/cu m of expanded bed volume. The upflow velocity is 0.4 cm/s and the reactor has an empty bed contact time of 10 minutes at design flow. Each reactor has a design capacity of 7.5 mL/d. The biofilm is grown on a medium of sand with an effective size of 0.6 mm and a uniformity coefficient of 1.2. The reactor has a perforated concrete underdrain, 0.6 meters of support gravel, and 1.2 m of sand. Following a two-month startup period, the facility consistently removed 95 to 100% of the nitrate-N. Several requirements were identified from the first year of operation: (1) an effective method of measuring and controlling biofilm growth; (2) a reliable methanol feed system; and (3) if very low concentrations of nitrate-N must be produced, then consideration should be given to scrubbing the off gases and eliminating the potential for odors. It was concluded that the fixed-film expanded bed denitrification system is a cost-effective method of reducing nitrate-N. (MacKeen-PTT)

BATCH BIODEGRADATION OF INDUSTRIAL ORGANIC COMPOUNDS USING MIXED LIQUOR FROM DIFFERENT POTWS.
New Jersey Inst. of Tech., Newark. Dept. of Chemical Engineering.
G. A. Lewandowski.
Research Journal of the Water Pollution Control Federation JWPFA5, Vol. 62, No. 6, p 803-809, September/October 1990. 7 fig, 4 tab, 47 ref.

Descriptors: *Activated sludge, *Biodegradation, *Biological wastewater treatment, *Organic compounds, *Waste treatment, *Wastewater treatment, Biological treatment, Chlorinated hydrocarbons, Kinetics, Microbial degradation, Mixed liquor, solids, Publicly owned treatment works.

The biological treatment of organic compounds with mixed liquor from different publicly owned treatment works (POTWs) was studied. Experiments conducted using several 5-L batch reactors involved the degradation of single compounds and mixtures of compounds with two different mixed liquors. One mixed liquor came from a municipal treatment plant with a throughput of 9.5 ML/d of domestic waste; the other came from a plant that treats 95 ML/d of waste that is 55% industrial on a biological oxygen demand basis, including about 227 kg/d of phenol. Microorganisms from the domestic treatment plant degraded chlorinated hydrocarbons (2-chlorophenol, 2,6-dichlorophenol and 2,4-D) at rates that were virtually the same as those for the plant handling industrial waste. The phenol degradation rates were the same, even though one plant had experienced significant prior exposure. The dominant microbial populations were also similar, both before and after phenolic exposure. Microbial adaptation to the compounds was quite rapid, resulting in a two-fold to five-fold increase in the average degradation rates after only the second exposure in a batch reactor. When multiple substrates were tested, the individual compound degradation rates in the mixture were very similar to the degradation rates as sole carbon source. The amount of throughput and the magnitude of degradation rates indicate the potential of the plant handling industrial waste to treat significant quantities of the compounds tested. OPERATIONAL WATER QUALITY MANAGEMENT: CONTROL OF STORM SEWAGE AT A WASTEWATER TREATMENT PLANT.
P. Lessard, and M. B. Beck.
Research Journal of the Water Pollution Control Federation JWPFA5, Vol. 62, No. 6, p 810-819, September/October 1990. 9 fig, 10 tab, 36 ref.

Descriptors: *Storm wastewater, *Wastewater facilities, *Wastewater management, *Wastewater treatment, Control systems, Model studies, Storm water management, Storm-overflow sewers, Water quality control.

In almost all wastewater treatment plants it is customary to control the effects of a surge of stormwater by bypassing flows above a certain threshold directly to the receiving waters. The threshold is normally set at three times the dry weather flow (3DWF) of wastewater, and in the U.K., is usually accompanied by the installation of storm tanks between the overflow and receiving water. A dynamic model of treatment plant behavior was applied in a comparative study of several alternative strategies of stormwater control. The model comprises the typical unit processes of the liquid train of the plant: storm tanks, primary clarifiers, aeration basins, and secondary clarifiers. The control options include: alternative locations for the overflow and storm tanks, variations on the theme of the 3DWF concept, alternative modes of operation of the storm tanks, and the manipulation

overflow settings during the event. The results dicate the virtue of allowing for flexibility in ant designs, especially with respect to: incorpoing more than one overflow location, the need different strategies for different events and ferent categories of pollutants, and the potential the beneficial use of real-time forecasting and ntrol of events of low intensity and long dura-n. cent years, Milwaukee's water quality has ated much interest. Area residents are awaite completion of the Milwaukee Metropolitan rage District's (MMSD) 2.25 billion Water ion Abatement Program (WPAP), and city s hope to make a revitalized Milwaukee the focal point of downtown redevelopment. e primary agency charged with protecting water resources, the MMSD has a responsito track water quality. The district's surface quality monitoring program provides more decade of baseline data. At its inception in the monitoring program covered eight samlocations on the metro area's three rivers and sampling locations from Milwaukee's Outer r to Lake Michigan. Today the program passes six major survey types and 64 samlocations. The district's monitoring program ses two major areas: the impact of effluent he district's two wastewater treatment plants e overall water quality within the district. f the sites are visited every other week, and he aid of computers, MMSD technicians can the water quality conditions of specific and days against data collected up to a earlier. Water quality testing parameters o four broad categories: conventional testomonitoring by exposing daphnia magna, Ceriodaphnia dubia and fathead minnows; tracking of conservative tracers (i.e., chloride, specific conductance, total alkalinity, and hardness); and heavy metals testing monitoring the 13 EPA priority pollutant metals. In recent years, other public agencies have used the data extensively as a basis for planning. By providing such long-term, comprehensive information to a wide array of users, the monitoring program has helped promote the wise use of limited resources to improve water quality. (VerNooy-PTT)

NORTH CAROLINA PLANT SOLVES TEXTILE-WASTEWATER PROBLEMS.
East Burlington Wastewater Treatment Plant, NC.
A. R. Kornegay, and C. Sell.
Water Environment & Technology WAETEJ, Vol. 2, No. 10, p 26, October 1990.

Descriptors: *Dyes, *Industrial wastewater, *Textile mill wastes, *Wastewater facilities, *Wastewater treatment, Activated carbon, Bioassay, Monitoring, North Carolina, Wastewater composition, Water pollution prevention, Water quality standards.

The East Burlington (NC) wastewater treatment plant is a 12 mgd facility that was upgraded 11 years ago to deal with textile-manufacturing wastewaters that comprised up to 60% of the flow. However, as recently as 6 years ago, the plant's effluent averaged 23 mg/L biological oxygen demand (BOD), 86 mg/L total suspended solids (TSS), and 7.1 mg/L ammonia nitrogen (NH3-N). All three parameters violated East Burlington's summer discharge permit. The plant was upgraded to deal with the problem of old textile plants in the area discharging highly colored effluent, by installation of a PACT system and wet-air regeneration unit. The PACT system follows treatment in an aerated equalization basin and primary treatment, and involves the addition of powdered activated carbon to the aeration chambers of the activated-sludge system. In effect, physical and biological treatment take place simultaneously, successfully removing color, biodegradeables, and non-biodegradeables. Several changes in equipment and operational practices relating to solids control have improved performance. Improvements have greatly reduced foam buildup on the final clarifiers, and the use of skimmers on the secondary clarifiers protects the final filters and has helped lower effluent suspended solids. Before the upgrade, the river was a dark black color. Now, discharge from the plant is crystal clear and the river quality is much improved. Biomonitoring of the effluent with Daphnia is now required, and the plant is passing these new toxicity tests without any problems. (VerNooy-PTT)

FLUID BEHAVIOR/WASTE MANAGEMENT IN LOW-GRAVITY ENVIRONMENTS.
Air Force Academy, CO. Dept. of Civil Engineering.
A. M. Wachinski, and K. T. Preston.
Water Environment & Technology WAETEJ, Vol. 2, No. 10, p 56-58, October 1990. 2 fig.

Descriptors: *Fluid mechanics, *Gravity studies, *Satellite technology, *Wastewater management, *Wastewater renovation, *Wastewater treatment, Buoyancy, Convection, Design criteria, Microgravity, Sedimentation, Systems engineering, Waste management.

Current plans for the US space station are to recycle as much wastewater as possible to reduce shuttle resupply requirements. However, fluid behavior in space differs markedly from that in a gravity-dominated environment. The term zero-G strictly means a total absence of gravity where the net contact force on the system under consideration is zero. Aboard an orbiting spacecraft objects behave as they would in a very weak gravitational field (in microgravity), and space engineers must account for the effects. Basic phenomena such as buoyancy, settling, convection, mixing and diffusion are considerably different in a microgravity environment. Multi-phase water systems, such as water and air or water and suspended solids, will pose special design considerations in a microgravity environment. In low gravity or microgravity, body forces approach zero, consequently hydrostatic pressure, buoyancy, convection, and sedimentation approach zero. A discussion is presented of these forces. The characteristics of microgravity fluid behavior that affect waste management stem from one fact--there is an absence of body forces. Sedimentation and flotation are eliminated, while surface tension and capillarity play the major role in fluid behavior. The changes are significant for all fluid processes, but they are extremely critical in spacecraft environmental design. (VerNooy-PTT)

USING PROGRAMMABLE LOGIC CONTROLLERS.
Central Contra Costa County Sanitary District, Martinez, CA.
A. R. Grieb, and G. Williams.
Water Environment & Technology WAETEJ, Vol. 2, No. 10, p 64-67, October 1990. 8 fig.

Descriptors: *Automation, *Control systems, *Electronic equipment, *Process control, *Programmable logic controllers, *Wastewater facilities, California, Computer programs, Monitoring, Project planning, Secondary wastewater treatment, Sludge drying.

Programmable logic controllers (PLCs) are a good choice for equipment and process control in wastewater treatment plants. Central Contra Costa Sanitary District in Martinez, CA, operates a 45-mgd secondary treatment plant designed during the late 1960s. In 1986, the district constructed a new furnace-control room and, in doing so, replaced all of the relays in the existing control panels with a small PLC. For the furnace-control room, a PLC was chosen as a relay replacement; however, the PLC was also used instead of extending all of the wires from the existing control panels to the new furnace-control room. Next the district specified a PLC system for its dewatering system to control new sludge-dewatering centrifuges and associated equipment. With PLCs controlling the centrifuges, the district began using PLCs for PID control, to adjust the differential speed of the centrifuge's scroll conveyor. This control maintains a consistent sludge-cake density. One of the main advantages in a PLC system is the ease with which the system can be modified. Another advantage is the ease of PLCs in troubleshooting. With the programming device connected to the PLC, the ladder logic can be viewed on a screen showing the current flow instead of measuring voltages. Discussion is made of the process of getting from the planning stage of a PLC system to a working system, including specifications, testing, and operator training. Since the system has been in operation, many new uses have been found. Sludge-incinerator hearth-burner status was brought in to the central computer so it could be monitored and status signals for equipment were sent to the alarm panel in the furnace-control room. The district has also evaluated the interface to see if it could replace the existing telemetry system. (VerNooy-PTT)

BIODEGRADATION OF TOXIC ORGANICS: STATUS AND POTENTIAL.
Clemson Univ., SC. Dept. of Environmental Systems Engineering.
C. P. L. Grady.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 805-828, 1990. 1 fig, 2 tab, 82 ref.

Descriptors: *Biodegradation, *Biological treatment, *Organic compounds, *Wastewater treat-

ment, Biotechnology, Decision making, Literature review, Mathematical models, Microbiological studies, Waste management, Waste treatment.

The ability of biological treatment systems to degrade toxic organic compounds is assessed through a review of the literature. While much general information is available, there is little kinetic information that can be used directly by engineers making decisions about process alternatives. Nevertheless, useful kinetic information can be obtained from biodegradation studies in which the toxic compound of interest serves as the sole substrate for microbial growth. A scheme is proposed whereby such information can be used in mathematical models to predict the extent to which the toxic compounds can be removed from complex waste streams. A methodology is proposed whereby the impacts of the toxic compounds on the biodegradation of the biogenic organic material in the waste streams can be predicted. New information about environmental biotechnology is being generated by biologists faster than engineers can assimilate and apply it. Thus, close alliances must be formed between engineers and scientists to fully exploit the potential offered by biotechnology. (Author's abstract)

SIMPLE SOLUTIONS FOR STEADY-STATE BIOFILM REACTORS.
Clemson Univ., SC. Dept. of Environmental Systems Engineering.
P. S. Golla, and T. J. Overcamp.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 829-836, 1990. 1 fig, 9 ref, append.

Descriptors: *Biofilm reactors, *Biological reactors, *Model studies, *Wastewater reactors, *Wastewater treatment, Biofilms, Biological treatment, Biological wastewater treatment, Limiting factors, Substrates.

Simple analytical models for use in preliminary calculations are developed to approximate the steady-state concentration and biofilm thickness in a biofilm reactor. The models presented considered the case in which a single substrate limits growth. These models assume that the flux of substrate to the biofilm has a first order dependence on the bulk substrate concentration. This assumption restricts the use of the models to low initial substrate concentrations. One of the models assumes plug flow, and the other incorporates longitudinal dispersion of substrate. The models allow the substrate concentration to approach the minimum rate limiting concentration and the biofilm thickness to approach zero as predicted by the steady-state theory. Predictions of these models are compared to those of a steady-state numerical model. For an example taken from the literature, the solution of the model with longitudinal dispersion is in good agreement with the numerical solution. (Author's abstract)

FREEZING OF WATER AND WASTEWATER SLUDGES.
Duke Univ., Durham, NC. Dept. of Civil and Environmental Engineering.
P. A. Vesilind, and C. J. Martel.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 854-862, 1990. 5 fig, 20 ref.

Descriptors: *Freezing, *Sludge drying, *Wastewater management, *Wastewater treatment, Crystallization, Freeze-thaw tests, Physical treatment, Sludge, Sludge treatment, Temperature.

When sludge is allowed to freeze slowly and then thaw, its dewatering properties are usually greatly improved. The mechanisms by which this improvement occurs are not well understood. Therefore, the authors have proposed a conceptual model for how sludge freezes. The effectiveness of freeze/thaw is measured using the capillary suction apparatus with the results indicating that colder temperatures, longer freezing times and slower freezing rates all have a beneficial effect. These results suggest that if freeze/thaw is to be used commercially, thin layers of sludge must be frozen for long periods of time, thereby promoting the growth of crystals that will exclude the solid particles and promote particle aggregation. CONTINUOUS PRE-ANOXIC AND AEROBIC DIGESTION OF WASTE ACTIVATED SLUDGE.
Maryland Univ., College Park. Dept. of Civil Engineering.
O. J. Hao, and M. H. Kim.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 863-879, 1990. 11 fig, 5 tab, 19 ref, append.

Descriptors: *Activated sludge process, *Aerobic digestion, *Sludge digestion, *Sludge stabilization, *Wastewater treatment, Biomass, Denitrification, Nitrates, Nitrification, Suspended solids, Volatile solids.

Conventional aerobic sludge stabilization requires extensive energy input. Incorporation of endogenous nitrate respiration (ENR) into the aerobic-digestion system offers an energy saving advantage. In the ENR system, nitrate instead of oxygen is utilized for biomass destruction. Continuous pre-anoxic and aerobic digestion of waste activated sludge was studied to evaluate its effectiveness for volatile suspended solids (VSS) destruction and nitrogen removal. The ENR occurs in the anoxic digester because of the recycling of nitrate from the aerobic digester. The anoxic effluent, in turn, provides a high pH and adequate buffer capacity for enhancing the subsequent aerobic decay and nitrification. Two experimental runs, differing in hydraulic detention time in anoxic and aerobic tanks, are conducted with the same recycling rate. The results indicate that total nitrogen removal is approximately 25%, with 40% VSS destruction. The denitrification/nitrification efficiencies and rates were also determined. A mathematical model developed from the mass balance of biomass, ammonium, and nitrate can reasonably predict the transient responses of these parameters. (Author's abstract)

TESTING EXPERT SYSTEM FOR ACTIVATED SLUDGE PROCESS CONTROL.
A.T. and T. Bell Labs., Naperville, IL.
W. Lai, and P. M. Berthouex.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 890-909, 1990. 6 tab, 44 ref. EPA Agreement No. CR-812655-01-0.

Descriptors: *Activated sludge process, *Computer programs, *Expert systems, *Process control, *Wastewater treatment, Data interpretation, Information management, Sludge digestion, Wastewater facilities.

The wastewater treatment plant operator's most difficult problem is collecting, storing, manipulating and interpreting data; an information management problem. The operator's performance in controlling the treatment process can be improved if he is equipped with a convenient and efficient method for extracting useful information from the data. A rule-based expert system within an integrated information management system is presented in this article. The expert system only considers the activated sludge process, but the information system is for the entire treatment plant. The expert system provides the operator with timely advice based on the latest available process data as interpreted by a set of rules constructed with the help of experienced and skilled operators. Case studies are presented to help develop an approach for refining the control rules as well as testing their accuracy and effectiveness. The expert system consistently reproduced the expert operators decisions and performed better than nonexpert operators. (Lantz-PTT)

BOUNDED IMPLICIT ENUMERATION FOR WASTEWATER-TREATMENT SYSTEMS.
North Carolina Agricultural and Technical State Univ., Greensboro. Dept. of Civil Engineering.
S. Y. Chang, and S. L. Liaw.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 910-926, 1990. 6 fig, 5 tab, 49 ref.

Descriptors: *Mathematical models, *Model studies, *Systems engineering, *Wastewater treatment, Computer programs, Cost-benefit analysis, Mathematical studies.

A wastewater treatment system can be represented by a multistage configuration consisting of a variety of unit processes from various stages. The number of treatment combinations may be very large when the number of unit processes in a stage and the number of stages in a system increase. Enumeration techniques, e.g., total enumeration and implicit enumeration, have been used to eliminate infeasible treatment combinations and to identify the least cost treatment system. A bounded implicit enumeration approach is proposed to make the implicit enumeration more efficient. A lower bound is calculated at each stage and added to the up-to-date objective function value to eliminate more combinations before reaching the final stage. The results for two wastewater treatment system synthesis models indicate that the bounded implicit enumeration is consistently more efficient than the total and implicit enumeration approaches in identifying least cost and feasible treatment alternatives. NEW APPROACH FOR OPTIMIZATION OF URBAN DRAINAGE SYSTEMS.
Bradford Univ. (England). Dept. of Civil Engineering and Structural Engineering.
G. Li, and R. G. S. Matthew.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 927-944, 1990. 4 fig, 5 tab, 16 ref, append.

Descriptors: *Drainage systems, *Optimization, *Urban drainage, *Urban runoff, Construction, Costs, Design standards, Flow rates, Pipes, Pumping plants, Surface runoff.

A new approach for the optimization of urban drainage systems, including the optimal selection of layout using the searching direction method and the optimal design of a given layout by discrete differential dynamic programming (DDDP), were developed and applied to a typical field study. It was found that the inclusion of such hydraulic factors as flow rate, the sizes and gradients of pipes, and the effect of on-line pumping stations into consideration, is very important in urban drainage systems layout selection. Also, the optimization of urban drainage systems, including optimal layout selection, can achieve much greater construction cost savings than that without the inclusion of layout optimization. It was also demonstrated that the minimum buried depth design is not the global optimum design. Rather, the global optimum design is the alternative of the optimal balance among the buried depth, and the number and locations of on-line pumping stations. (Author's abstract)

CHARACTERIZATION OF ACTIVATED SLUDGE FOAMS FROM TWO PLANTS.
Blue Plains Wastewater Treatment Plant, Washington, DC.
G. T. Fahmy, and O. J. Hao.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 991-997, 1990. 2 fig, 2 tab, 27 ref.

Descriptors: *Activated sludge process, *Foaming, *Wastewater treatment, Adenosine triphosphate, Biomass, Carbohydrates, Nitrogen, Sludge digestion, Volatile solids.

Activated sludge (AS) foaming problems have recently received considerable attention. Excessive foaming not only causes deterioration in effluent quality, but also presents operational and mainte-

problems, and possible health hazards. The ence of sludge foaming has been associated ifferent and often conflicting operational and nmental factors. The objective of this study o characterize activated sludge foams in f volatile content, lipid, nitrogen and carbo- e composition, adenosine triphosphate level, hydrolysis characteristics, and sub- utilization. Excessive foams must be re- promptly, otherwise the recycle of foams d to more severe scum production. Conse- the results of foam hydrolysis and its treat- may provide an alternative for ultimate disposal. For the purpose of comparison, liquor (ML) was also used for these parame- asurements. The results indicate that foam ntain a significant amount of substrate and he foam contents vary from plant to plant en within the same plant. The microbial of AS foam was found to be similar to that These factors provide a perfect environ- nd abundant substrate for foam causing bac- at can degrade many of the organic com- previously accumulated at the air-water e. The net result is that an active biomass ion exists at the surface of the aeration at has a significant impact on the system and hence substrate removal. In addition, m biomass should be included in the bio- ventory used to calculate the solids reten- e. The disposal of AS foams presents addi- perational and maintenance problems. Hy- of foam using low pH plus heat treatment o be a viable alternative for foam disposal. iminates the problem of transferring foam organisms to the anaerobic digester. Hy- d foam can be effectively treated in an d sludge plant with little impact on the moval efficiency. (Lantz-PTT)

INVESTIGATION OF REST AREA REQUIREMENTS: APPENDIX-PERTINENT REST AREA LITERATURE.
Texas Univ. at Austin. Center for Transportation Research.
W. T. Straughan, D. W. Fowler, and K. W. Perry.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-194807. Price codes: A03 in paper copy, A01 in microfiche. Research Report 442-1, Volume 2, November 1987. 62 p, 66 ref, append. Texas State Department of Highways and Public Transportation Project 3-18-86-442.

Descriptors: *Data acquisition, *Highways, *Literature review, *Municipal water, *Surveys, *Wastewater management, Design standards, Site selection, Water supply.

Rest areas are an important part of highway systems, particularly on the interstate systems. Based on the findings presented in previous reports, recommended design procedures are presented. Recommendations include: spacing, site requirements, example architectural designs, materials, mechanical systems, and operation and maintenance. Recommendations for energy sources, water systems, and wastewater systems are also made. The appendix contains detailed information on surveys and interviews. (Lantz-PTT)
W91-02620

WETLAND AREAS: NATURAL WATER TREATMENT SYSTEM (JAN 78 - AUG 89). CITATIONS FROM THE POLLUTION ABSTRACTS DATABASE.
Davis (J.J.) Associates, Inc., McLean, VA.
Available from the National Technical Information Service, Springfield, VA 22161, as PB90-862244. Price codes: N01 in paper copy, N01 in microfiche. March 1990. 99p.

Descriptors: *Artificial wetlands, *Bibliographies, *Environmental effects, *Environmental protection, *Path of pollutants, *Wastewater treatment, *Wetland treatment, *Wetlands, Agricultural runoff, Flooding, Habitats, Water pollution effects.

This bibliography contains citations concerning the ability of salt marshes, tidal flats, marshlands, bogs, and other wetland areas to degrade, absorb, filter, consume, mitigate natural and man-made pollution and wastes, while maintaining their ability to provide refuge and breeding grounds for wildlife. The ecology, biochemistry, and viability of naturally occurring and artificially established wetlands as water-treatment systems and wildlife areas are considered. The effects of individual pollutants, environmental factors, species diversity, and cleansing ability of wetland areas on the potential for wildlife refuge, sewage treatment, treatment of industrial and municipal wastes, handling agricultural runoff, mitigating accidental spills, and flooding are discussed. This updated bibliography contains 243 citations, 21 of which are new entries to the previous edition. (Author's abstract)
W91-02642

WASTEWATER TREATMENT: CHEMICAL INDUSTRY (JAN 70 - SEP 89). CITATIONS FROM THE POLLUTION ABSTRACTS DATABASE.
Davis (J.J.) Associates, Inc., McLean, VA.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-871057. Price codes: N01 in paper copy, N01 in microfiche. September 1989. 79p.

Descriptors: *Bibliographies, *Chemical wastes, *Industrial wastewater, *Wastewater treatment, Activated carbon, Biological treatment, Fertilizers, Mercury, Pesticides.

This bibliography contains citations concerning wastewater treatment in the chemical industry relative to a wide variety of industrial pollutants. Biological treatments including carbon additives are described relative to effectiveness. The removal of mercury and its compounds are included, as well as associated problems and recommendations from fertilizer and pesticide pollution. This updated bibliography contains 250 citations, 16 of which are new entries to the previous edition. (Author's abstract)
W91-02644

PULPING EFFLUENTS: BIOLOGICAL TREATMENT (JAN 76 - SEP 89). CITATIONS FROM THE PAPER & BOARD, PRINTING & PACKAGING INDUSTRIES RESEARCH ASSOCIATION.
Davis (J.J.) Associates, Inc., McLean, VA.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-871248. Price codes: A01 in paper copy, A01 in microfiche. September 1989. 31p.

Descriptors: *Bibliographies, *Biological wastewater treatment, *Pulp and paper industry, *Pulp wastes, *Wastewater treatment, Design criteria, Management, Pilot plants, Solid wastes, Toxicity.

This bibliography contains citations concerning effluent and wastewater biological treatment and disposal in the pulping industry. Effluent toxicity; treatment plant management, treatment systems and equipment design; combined mechanical and biological treatment processes; biological degradation treatment in chemical pulp mills; and the handling and disposal of solid wastes are among the topics discussed. Performance evaluations of biological treatment processes in domestic and foreign plants in full scale operation and pilot programs are considered. This updated bibliography contains 48 citations, 10 of which are new entries to the previous edition. (Author's abstract)

REMOVAL AND FATE OF RCRA AND CERCLA TOXIC ORGANIC POLLUTANTS IN WASTEWATER TREATMENT.
Cincinnati Univ., OH. Dept. of Civil and Environmental Engineering.
S. J. Bhattacharya, R. V. R. Angara, D. F. Bishop, R. A. Dobbs, and B. M. Austern.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-195200/AS. Price codes: A08 in paper copy, A01 in microfiche. Report No. EPA/600/2-89/026. June 1989. 159p, 1 fig, 14 tab, appends.

Descriptors: *Activated sludge process, *Organic pollutants, *Testing procedures, *Toxic wastes, *Wastewater treatment, Aliphatic solvents, Benzene, Biodegradation, Chemical oxygen demand, Suspended solids.

Two separate studies were conducted to investigate the removal and fate of 28 selected Resource Conservation and Recovery Act (RCRA) compounds (0.25 mg/L of each compound) and 19 selected CERCLA compounds (0.5 mg/L of each compound) in conventional activated sludge treatment. In each study, two pilot-scale (35 gpm) activated sludge systems (sludge retention time: 4 days for RCRA study and 8 days for CERCLA study) were operated in parallel at the U.S. EPA Test and Evaluation Facility in Cincinnati, Ohio. One system was spiked continuously with either RCRA or CERCLA toxics to produce an acclimated biomass; the other was spiked intermittently with the same toxics and sampled to determine performance under unacclimated conditions. The selected RCRA or CERCLA compounds did not cause any adverse effects on chemical oxygen demand (COD) and suspended solids (SS) removal. The concentrations of organics (RCRA study) in air emissions indicated that the chlorinated aliphatic solvents were essentially volatilized into the plant air emission stream, whereas the aromatic volatile benzenes were substantially degraded. Pesticides and phthalates are removed by both sorption on sludges and by biodegradation. These air emission results qualitatively confirm results from earlier bench scale studies which had superior analytical reliability but without the real world sampling and wastewater matrix effects. (Author's abstract)

WASTE WATER, INFILTRATION-PERCOLATION FOR AQUIFER RECHARGE OR WATER RE-USE.
Montpellier-2 Univ. (France). Lab. d'Hydrologie et de Modelisation.
F. Brissaud, F. Lefevre, C. Joseph, Z. Alamy, and A. Landreau.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 443-455, 4 fig, 14 ref.

Descriptors: *Aquifer management, *Groundwater management, *Groundwater resources, *Wastewater renovation, *Wastewater treatment, *Water resources management, *Water reuse, Effluents, France, Groundwater recharge, Irrigation water, Percolating filters, Percolating water, Pollution load, Self-purification, Water storage.

Renovated wastewater may be stored for reuse as irrigation water during the dry season. Infiltration-percolation is a rustic and extensive purifying technique which is capable of completely oxidizing and decontaminating wastewater. It is particularly adapted to wastewater reutilization projects and to the recharge of shallow groundwater planned to be used for the interseasonal storage of purified water. The wastewater is purified during its percolation through unsaturated sandy media. An exemplary model of the convective renewal of oxygen in the gaseous phase supplies the basis of the designs and, for only slightly-loaded or medium-loaded wastewater, of the dimensions of the infiltration-percolation plants. An experiment confirmed that this technique is capable of purifying heavily-loaded effluents (primary effluents with an oxygen demand of more than 250 mg/L) on the condition that hollow structures are introduced into the filtering beds. This laboratory work was followed by implementation of this technique into actual operations in France, with the aim of improving knowledge on the subject of basin-supplying systems and of monitoring the evolution of the gaseous oxygen stock in the filtering medium during purification. The various technologies are currently being tested at these stations. (See also W91-02672) (Author's abstract)

COMMITMENT TO MONITORING AND SAMPLING.
Lakeland, FL.
T. Lokken.
Water Engineering and Management WENMD2, Vol. 137, No. 9, p 28-31, September 1990. 2 fig, 1 tab.

Descriptors: *Florida, *Wastewater analysis, *Wastewater facilities, *Wastewater management, *Wastewater treatment, *Water quality monitoring, *Water sampling, Economic aspects, Industrial wastewater, Pretreatment of wastewater, Priority pollutants, Process control, Sludge.

The wastewater treatment facilities of the City of Lakeland, Florida, are among the most complex in the state, yet they are also recognized as being among the most effective and efficient. One major reason for this efficiency is commitment to thorough monitoring and sampling which exceeds Environmental Protection Agency (EPA) requirements but yields major benefits in treatment quality and cost savings. The key to successful process control at the plants is sampling. Careful monitoring prevents energy waste and allows more efficient use of materials. Monitoring also insures the most effective processing of the wastewater. Nutrients and nitrogen levels which affect biological activity can be examined and adjustments made if necessary. Data gathered through monitoring is used to control the activated sludge system, anaerobic digestion, and sludge thickening, and to control chemical usage. Monitoring is also used to track costs for such programs as odor control. Efficiency of processes is tracked by monitoring the quality of influent and effluent. In addition to in-plant monitoring, the Lakeland wastewater treatment program includes an extensive industrial monitoring program. Pretreatment programs conducted by area industries are monitored to insure that wastewater form the industrial plants meets EPA limits on heavy metals, cyanide and other priority pollutants which could damage the treatment plants. DIGESTER GAS IS ALTERNATE FUEL.
San Antonio Dept. of Wastewater Management, TX.
F. Rodriguez.
Water Engineering and Management WENMD2, Vol. 137, No. 9, p 32-33, September 1990. 1 fig.

Descriptors: *Anaerobic digestion, *Digester gas, *Energy recovery, *Energy sources, *Fuel, *Wastewater facilities, *Wastewater treatment, Insurance, Process control, San Antonio, Texas.

Dos Rios Wastewater Treatment Plant is an expansion facility that was built to service part of the growing community of San Antonio, Tex. The San Antonio wastewater treatment facilities require two medium-sized hot-water boilers and one small low-pressure steam boiler. Previously, the city was flaring the anaerobic gas supply and losing all energy potential. The city currently uses the heat to maintain a controlled environment in the digester to produce gas and then, fires the boilers with the gas in order to produce heat. The digester gas system uses a dual canister burner that is designed for separate combustion control for two gases with different fuel characteristics. The dual canister housing arrangement applies specifically to gases with low heating value. The separate burner arrangement-where the two gases do not use the same orifice ring-is critical to proper combustion setting and efficiency. The multi-gas system provides separate fuel-handling systems for each fuel. By using separate fuel trains, fuel consistency is maintained and problems associated with mixing of fuels is avoided. Also, by providing fuel trains that do not share any common piping, automatic change-over is easily incorporated. Furthermore, separate fuel trains comply with current insurance regulations. BIODEGRADATION OF P-NITROPHENOL IN AN AQUEOUS WASTE STREAM BY IMMOBILIZED BACTERIA.
Monsanto Environmental Sciences Center, St. Louis, MO.
M. A. Heitkamp, V. Camel, T. J. Reuter, and W. J. Adams.
Applied and Environmental Microbiology AEMIDF, Vol. 56, No. 10, p 2967-2973, October 1990. 5 fig, 26 ref.

Descriptors: *Activated sludge process, *Bacteria, *Biodegradation, *Nitrophenols, *Wastewater treatment, Adsorption, Microbial degradation, Path of pollutants, Pseudomonas, Toxicity, Waste treatment.

Microbiological analyses of activated sludge reac tors after repeated exposure to 100 mg of p-nitro phenol (PNP) per liter resulted in the isolation o three Pseudomonas species able to utilize PNP as sole source of carbon and energy. Cell suspension of the three Pseudomonas sp., designated PNP1 PNP2, and PNP3, mineralized 70, 60, and 45% of a 70 mg/L dose of PNP in 24, 48, and 96 h. Mas balance analyses of PNP residues for all three cultures showed that undegraded PNP was < 1% (<50 microg); volatile metabolites, < 1%; cel residues, 8.4 to 14.9%; and water soluble metabo lites, 1.2 to 6.7%. A mixed culture of all three PNP-degrading Pseudomonas sp. was immobilized by adsorption onto diatomaceous earth biocarrie in a 1.75 L Plexiglas column. The column wa aerated and exposed to a synthetic waste strean containing 629 to 2513 mg of PNP per liter at flow rates of 2 to 15 ml/min. Chemical loading studies showed that the threshold concentration for acut toxicity of PNP to the immobilized bacteria wa 2100 to 2500 mg/L. Further studies at PNP con centrations of 1200 to 1800 mg/L showed that > 99, and 91 to 99% removal of PNP was achieve by immobilized bacteria at flow rates of 10 and 1 mL/min. These values represent hydraulic reten tion times of 48 to 58 min and PNP removal rate of 0.99 to 1.1 mg/h/g of biocarrier at 25 C unde optimal conditions. This study shows the success ful use of immobilized bacteria technology t remove high concentrations of PNP from aqueou waste streams. (Author's abstract)

DEGRADATION OF VINYL ACETATE B SOIL, SEWAGE, SLUDGE, AND THE NEWL ISOLATED AEROBIC BACTERIUM V2.
Bayreuth Univ. (Germany, F.R.). Lehrstuhl fue Mikrobiologie.
M. Nieder, B. Sunarko, and O. Meyer.
Applied and Environmental Microbiolog AEMIDF, Vol. 56, No. 10, p 3023-3028, Octobe 1990. 4 fig, 3 tab, 25 ref. Bundesministerium fu Forschung und Technologie Grant No. 0318839 I

Descriptors: *Biochemistry, *Biodegradatio *Fate of pollutants, *Path of pollutants, *Vin acetate, *Wastewater treatment, Bacteria, Chem cal reactions, Enzymes, Hydrolysis, Sludge, Sc chemistry, Wastewater.

Vinyl acetate is subject to microbial degradation the environment and by pure cultures, and can b hydrolyzed by samples of soil, sludge, and sewag at rates of up to 6.38 and 1 mmol/h/g (dry weigh under aerobic and anaerobic conditions. Fo yeasts and thirteen bacteria that feed aerobical on vinyl acetate were isolated, but in this stud the pathway of vinyl acetate degradation was fo lowed in bacterium V2. Vinyl acetate is first d graded to acetate, which is then converted acetyl coenzyme A and oxidized through the t carboxylic acid cycle and the glyoxylate bypas The key enzyme of the pathway is vinyl aceta esterase, which hydrolyzes the ester to acetate a vinyl alcohol. The latter isomerizes spontaneous to acetaldehyde and converts to acetate. The ace aldehyde is then disproportionated into ethan and acetate. The enzymes involved in the metab lism of vinyl acetate were studied in extrac Vinyl acetate esterase (K-m = 6.13 mM) was al active with indoxyl acetate (K-m = 0.98 mM providing the basis for a convenient spectrophot metric test. Substrates of aldehyde dehydrogena were formaldehyde, acetaldehyde, propionald hyde, and butyraldehyde. The enzyme was equal active with NAD+ or NADP+. Alcohol deh drogenase was active with ethanol (K-m = 0. mM) and was linked to NAD+. The molecul sizes of aldehyde dehydrogenase and alcohol deh drogenase were 145 and 215 kilodaltons, respe tively. eral methods of controlling odors from piggery ry have been used successfully, but aerobic tment is able not only to render odors inoffen-, but also, if more thorough, to remove them pletely. A manometric respirometer was used measure the long-term biochemical oxygen and of aerobically treated slurries. Different mes were used to treat each of two samples of slurry: a 1-day solids retention time with gen supplied to maintain dissolved oxygen at mg/L, and a 2-day solids retention time with a er aeration rate that controlled the redox poal at 181 mV and the dissolved oxygen at 0 L. Readings were taken daily for 80 days and once weekly for another 85 days. Calculations g data from the experiment estimate the effect the wind-mediated transfer of oxygen from the osphere into the slurry in a storage tank or on might have upon the time of the return of ffensive odor. Results show that the effect of l aeration is potentially far greater than that of a fourfold increase in the solids residence of the prior aerobic treatment. Storing aerobi-treated piggery slurry in a lagoon of maxi depth of 2 m could permit wind aeration cient to increase the period for which the s would not be offensive from a maximum of ays after a 4-day solids retention time treatto more than 180 days, even when the slurry had only a 1-day solids retention time treat. E OBSERVATIONS ON ORGANIC REAL IN AN SBR.
nal Univ. of Singapore. Dept. of Civil Engig.
Ng, and J. C. Tan.
ical Wastes BIWAED, Vol. 33, No. 3, p 9, 1990. 8 fig, 2 tab, 14 ref.

ptors: *Biodegradation, *Wastewater reacWastewater treatment, Adsorption kinetics, treatment, Biomass, Chemical oxygen demand, Microbial degradation, Mixed liquor solids, Volatile solids.

A laboratory-scale sequencing batch reactor was fed with synthetic wastewater based on sucrose to determine the biokinetics of the process. The values for maximum specific removal rate (u-max) and half-saturation constant (K-s) were found to be 0.32/hour and 563 mg/L, respectively, while the yield constant was determined to be 0.656 with a standard deviation of 0.102. Chemical oxygen demand removal was good. The relationship between the food:microorganisms (F/M) ratio and sludge volume index (SVI) was explored and results showed that increases in the F/M ratio led to decreases in SVI values. The initial adsorption of substrate was proportional to the amount of biomass in the reactor. Comparisons between changes in mixed liquor volatile suspended solids (MVLSS) and total viable count were made, and MVLSS was not found to be a good indicator for the viability of organisms in the reactor. PERFORMANCES OF DIGESTERS TREATING THE ORGANIC FRACTION OF MUNICIPAL SOLID WASTES DIFFERENTLY SORTED.
Barcelona Univ. (Spain). Dept. of Chemical Engineering.
J. Mata-Alvarez, F. Cecchi, P. Pavan, and P. Llabres.
Biological Wastes BIWAED, Vol. 33, No. 3, p 181-199, 1990. 4 fig, 6 tab, 22 ref. NATO Grant No. 0178/87 and CICYT Project PS87-0018.

Descriptors: *Anaerobic digestion, *Municipal wastes, *Organic matter, *Solid wastes, *Waste treatment, Biodegradation, Biogas, Kinetics, Mathematical studies, Methane, Thermodynamics.

When considering the anaerobic digestion of a given waste, both the kinetics and the thermodynamics of the process must be taken into account. The thermodynamic aspect is related to the biodegradability of the waste, and distinguishing between biodegradability and the rate of biodegradation is necessary. Digester performances are highly sensitive to the quality of the feed. To evaluate the real reactor performance, the bioprocess efficiency, defined as the percentage of the maximum biodegradation achievable, is examined. This parameter takes into account the kinetics of the process and the biodegradability. Biodegradation kinetics, measured through a first-order kinetic constant for the source-selected organic fraction municipal solid waste (SS-OFMSW), is around five to ten times larger than that of fresh mechanically-selected OFMSW. The ultimate biogas yield is also 2.5 times larger for SS-OFMSW than for MS-OFMSW. Bioprocess efficiency can achieve very large values (around 95 to 99% in both cases). Hydraulic retention time has a small influence on bioprocess efficiency if it is larger than 15 days. Lower yields are obtained if the MS-OFMSW has been precomposted. (Brunone-PTT)

ACUTE TOXICITY OF HEAVY METALS TO AEROBIC DIGESTION OF WASTE CHEESE WHEY.
Messina Univ. (Italy). Dipt. di Chimica Organica e Biologica.
G. Cimino, and C. Caristi.
Biological Wastes BIWAED, Vol. 33, No. 3, p 201-210, 1990. 3 fig, 6 tab, 14 ref.

Descriptors: *Aerobic digestion, *Food-processing wastes, *Heavy metals, *Toxicity, *Waste disposal, *Waste treatment, *Wastewater treatment, Acidity, Activated sludge, Biochemical oxygen demand, Dairy industry, Synergistic effects.

Cheese whey constitutes a major waste disposal problem for the dairy industry throughout the world. Effects of the acidity and of metal ions on the metabolic activity of activated sludge from waste cheese whey biological treatment, have been determined. The 10% and 50% inhibitory concentrations were evaluated for each ion. In decreasing order of toxicity, two groups were found: Hg(2+) > Cd(2+) > CrO4(2-) > Cr(3+); and Pb(4+) > Zn(2+). A discrepancy in results from other toxicity studies reveals the impossibility of defining, on an absolute scale, an order of toxicity for these ions. A very strong synergistic effect was noted in the mixed copper and zinc studies, revealing the difficulty of setting a water quality standard based on single toxic chemicals. (Author's abstract)
W91-02776

METHANOGENIC TOXICITY OF WOOD RESIN CONSTITUENTS.
Agricultural Univ., Wageningen (Netherlands). Dept. of Water Pollution Control.
R. Sierra-Alvarez, and G. Lettinga.
Biological Wastes BIWAED, Vol. 33, No. 3, p 211-226, 1990. 4 fig, 4 tab, 54 ref.

Descriptors: *Methanogenesis, *Resins, *Wastewater treatment, *Wood wastes, Anaerobic conditions, Bioassay, Inhibition, Sludge digestion, Toxicity.

The inhibitory effect of representative wood resin compounds on the activity of methanogenic bacteria is evaluated. Resin is, by definition, the mixture of wood components that are extractable with apolar solvents. Major resin constituents are long-chain fatty acids, terpenes, resin acids, lignans, and apolar phenols. The methanogenic inhibition was determined at a temperature of 30 C in standardized toxicity assays utilizing anaerobic granular sludge. An apolar phenol, 4-hydroxystilbene, was the most toxic of the compounds studied, with a 50% inhibiting concentration of 20 mg/L. Resin acids and volatile terpenes were also highly toxic to methanogenic activity. Concentrations causing 50% inhibition ranged from 43 to 330 mg/L. In contrast, triterpenes were non-toxic at relatively high concentrations, 1000 to 1300 mg/L. These results suggest that wood resin constituents play an important role in the anaerobic inhibition exerted by several forest industry wastewaters. (Author's abstract)

OZONATION OF O-CRESOL IN AQUEOUS SOLUTIONS.
Universidad de Extremadura, Badojoz (Spain). Dept. de Ingenieria Quimica y Energetica.
F. J. Beltran, J. M. Encinar, and J. F. Garcia-Araya.
Water Research WATRAG, Vol. 24, No. 11, p 1309-1316, November 1990. 8 fig, 5 tab, 27 ref. Comision Interminsterial de Ciencia y Tecnologia of Spain Grant No. PA85/332.

Descriptors: *Chemical properties, *Chemical reactions, *Cresol, *Ozonation, *Wastewater, *Wastewater treatment, Flux rate, Hydrogen ion concentration, Kinetics, Mass transfer, Partial pressure, Temperature effects.

The o-cresol aqueous solution ozonation of concentrations similar to those encountered in some wastewaters was studied. The ozone concentration was measured in the gas stream, iodometrically. During the absorption, ozone at the reactor outlet was also determined by the same procedure. In this way, the ozone absorption rate could be evaluated from the difference between the ozone molar flux rates at the reactor inlet and outlet. The degradation rate of o-cresol increased with temperature, pH, gas flow rate, agitation speed and ozone partial pressure. For a 0.001 M initial concentration of o-cresol a mass rate of 11.7 mg of ozone per minute leads to o-cresol conversions of about 70% in less than 20 min of ozonation, the liquid side mass transfer coefficient for the cuprous chloride-oxygen system (m/s) of the reactor is between 2.8 and 13.0/h. From the variation observed in the o-cresol ozonation yield with time a competitive effect of secondary reaction was shown. The ozone absorption rate was always higher than 3 times the maximum ozone absorption in organic-free water (value defined as reaction factor). This finding indicates that the reactions involved in the proximity of the gas-liquid interface and the kinetic regime is fast. (Author's abstract)

ELECTROLYTIC DECOMPOSITION OF CYANIDE EFFLUENT WITH AN ELECTROCHEMICAL REACTOR PACKED WITH STAINLESS STEEL FIBER.

National Tsing Hua Univ., Hsinchu (Taiwan). Dept. of Chemical Engineering.
S. P. Ho, Y. Y. Wang, and C. C. Wan.
Water Research WATRAG, Vol. 24, No. 11, p 1317-1321, November 1990. 10 fig, 9 ref.

Descriptors: *Cyanide, *Electrolysis, *Packed beds, *Wastewater reactors, *Wastewater treatment, Copper, Electrical resistance, Energy consumption, Silver nitrate, Titration.

An investigation was conducted to determine the feasibility of using a packed-bed electrochemical reactor with stainless steel fiber as electrodes to decompose cyanide-containing effluent. The analysis of cyanide variation during the electrolysis was made by standard titration method with AgNO3. The copper content was measured via atomic absorption spectroscopy. Every layer of the electrode was packed with 2 cm of stainless steel fiber. The anode and cathode layers were separated by a perforated lucite 12 cm diameter plate. The current collector was of the same shape and dimension as the plate and located on top of the separator. The results indicate that it is possible to reduce the cyanide content from 1400 mg/L to below 20 mg/L within 4-20 h with a 5-13 kw h/kg CN energy consumption. The cyanide destruction rate increased as the current was increased. It was found that the high current efficiency coupled with the low electrical resistance advantage due to the multiple layer electrode set-up results in a lower energy consumption than the conventional packed-bed reactor. The process can be accelerated with the existence of copper ions. (White-Reimer-PTT)

MICROBIAL NUMBERS AND ACTIVITY DURING INFILTRATION OF SEPTIC-TANK EFFLUENT IN A SUBSURFACE SAND FILTER.

Sveriges Lantbruksuniversitet, Uppsala. Institutionen foer Mikrobiologi.
M. Pell, F. Nyberg, and H. Ljunggren.
Water Research WATRAG, Vol. 24, No. 11, p 1347-1354, November 1990. 1 fig, 7 tab, 34 ref.

Descriptors: *Adenosine triphosphate, *Microbial degradation, *Nutrient removal, *Sand filters, *Septic tanks, *Wastewater treatment, Biochemical oxygen demand, Carbon dioxide, Chemical oxygen demand, Infiltration, Nitrogen, Phosphorus, Sweden.

A subsurface, 4-person sand-filter system for treating septic-tank effluent was subjected to conventional water analysis and to an extended microbial analysis of the filter material. Measured rates of CO2 production in the filter media suggest that the system has a good microbial capacity to degrade the organic matter in wastewater; the volume effectively treated depends on the BOD (e.g. 951 sq m/d at a BOD of 169 mg/L and 2851 sq m/d at a BOD of 74 mg/L). The actual load was 40 to 801 sq m/d. Based on viable counts of bacteria the amounts of P and N bound in the 13 +/-10 g dw/sq m viable biomass were calculated to correspond to the amounts produced by 1 person in <2 days. From the ATP levels in the sand, the active biomass was calculated to be 19 +/-15 g dw/sq m, indicating that the viable biomass also gives an accurate estimate of the active biomass. The levels of ATP in the sand-filter surface revealed that the loading of wastewater occurred unevenly. The high numbers of ammonium-oxidizing bacteria and denitrifying bacteria in the surface layer show that the system was predominantly operating aerobically and had a high potential for removing nitrogen. The microbial techniques used were sensitive enough to detect the decrease in biomass that occurred with increasing depth. Reduction of COD, P and N in the wastewater during infiltration were estimated to be 86, 70, and 60% respectively. These figures are considered to be overestimates, since analysis of Cl(-) showed that groundwater had leaked into the bed, diluting the effluent water. A correction factor for the dilution effect was therefore introduced. In addition, N and P from the surrounding arable land periodically leaked into the bed. The environment in the sand filter was sufficiently stable to ensure high microbial activity; thus the purifying capacity of septic-tank effluent should remain high throughout the year. SIMPLE METHOD TO DISTINGUISH BETWEEN POLYPHOSPHATE AND OTHER PHOSPHATE FRACTIONS OF ACTIVATED SLUDGE.

Technische Univ., Dresden (German D.R.). Sektion Wasserwesen.
D. Uhlmann, I. Roske, M. Hupfer, and G. Ohms.
Water Research WATRAG, Vol. 24, No. 11, p 1355-1360, November 1990. 8 fig, 1 tab, 16 ref.

Descriptors: *Activated sludge process, *Analytical methods, *Phosphates, *Polyphosphate, *Wastewater analysis, *Wastewater treatment, Fractionation, Lake sediments, Mixed liquor solids, Organophosphorus compound, Physicochemical properties.

The Psenner procedure of sequential extraction steps to quantify ecologically relevant phosphate fractions in lake sediments was applied to activated sludge from waste treatment plants for biological phosphate removal. The principal goal was to distinguish between proportions of chemical/physicochemical and biochemical processes in treatment plants with biological phosphate elimination. Using this method the phosphate fractions that may be distinguished are: (1) redox-sensitive phosphate, mainly bound to Fe(OH)3; (2) phosphate adsorbed to surfaces (Al2O3), exchangeable against OH(-), and alkali-soluble phosphate; (3) phosphate bound to CaCO3, MgCO3 and apatite; and (4) a fraction which hitherto was designated 'organically bound phosphate.' By means of nuclear magnetic resonance spectroscopy and by inclusion of a hot water extraction step it became evident that the 'organically bound phosphate' mainly contained polyphosphate (PP). In activated sludge samples with phosphate-accumulating bacteria, the PP content amounted to 80 mg/g mixed liquor volatile suspended solids. The difference in the PP concentration caused by an alternation of anaerobic and aerobic conditions (which is characteristic of biological phosphate removal) was reflected by corresponding differences in the proportion of the NaOH fraction. By combination of the Psenner fractionation and hot water extraction, indications of a significant proportion of PP in lake sediments have been found. (Author's abstract)

ACTIVATED SLUDGE PROCESS: A PROPOSED METHOD TO PREDICT PROCESS PARAMETERS.

W. H. Chapman.
Water Research WATRAG, Vol. 24, No. 11, p 1361-1363, November 1990. 4 ref.

Descriptors: *Activated sludge process, *Middle East, *Temperature effects, *Wastewater facilities, *Wastewater treatment, Design criteria, Mathematical models, Mixed liquor solids, Oxygen, Process control.

Sewage treatment plants in the Middle East operate on a wide temperature range which necessitates a revised approach to process control. Observations made while running these sewage treatment plants were used to develop a theory on activated sludge and to illustrate how the theory can be used to aid both operation and design of activated sludge plants. It was observed that as the ambient temperature increases, the sludge production and the power required for the process increase. If the mass balance for an activated sludge plant is then considered, and the system is in equilibrium, the material entering the plant is: (1) discharged in the effluent; (2) removed as surplus sludge; or (3) destroyed by respiration in the sludge. Equations subsequently derived to describe these relationships can be used to predict the operation of an activated sludge plant under varying site conditions. When a plant is being designed it is necessary to know the mean cell residence time (MCRT) for plant operation in order to calculate the respiration rate and the BOD load per K of mixed liquor solids at maximum and minimum temperatures. These figures can then be used to predict the surplus sludge produced and the power required under specific conditions. The variation in oxygen required and thus the degree of adjustment required on the aeration system can then be determined. When a plant is operated at constant mixed liquor solids, the power required varies to a greater degree than if the MCRT is kept constant. Allowing the mixed liquor solids to increase in winter within reasonable limits allows better use to be made of sludge treatment facilities. (White-Reimer-PTT)

KINETIC STUDY ON METHANOGENESIS B ATTACHED BIOMASS IN A FLUIDIZED BE

Kyushu Univ., Fukuoka (Japan). Dept. of Civ Engineering.
T. Kuba, H. Furumai, and T. Kusuda.
Water Research WATRAG, Vol. 24, No. 11, 1365-1372, November 1990. 8 fig, 6 tab, 11 re

Descriptors: *Fluidized beds, *Kinetics, *Metha ogenesis, *Wastewater reactors, *Wastewat treatment, Biomass, Comparison studies, Fat acids, Growth rates, Model studies.

The growth kinetic constants and the concentr tion of 'active' attached biomass in an anaerot fluidized bed, which decomposes acetic, propion and butyric acids were estimated. The fluidiz bed was operated as a methanogenic reactor w synthetic zeolite as support medium. The react was supplied with synthetic wastewater (1000 COD/L), a mixture of volatile fatty acids (VFA in the range of hydraulic retention time (HR from 0.25 to 2 days. After the effluent reached steady state in quality, batch experiments in bed reactor were conducted using acetic, propio ic and butyric acids as substrate in order to inve gate the decomposition characteristics of each s strate by the attached biomass. Detached biom from the support media was also used in ba experiments under the completely mixed condit in order to estimate parameter values of growth kinetics of the bacteria. The changes fatty acid concentrations with time were expres with the Monod growth model. The two kine parameters, maximum specific growth rates saturation constants, and 'active' biomass conc trations were obtained by the curve fitting meth The comparison of the measured concentration volatile suspended solids (VSS) and protein v the estimated 'active' biomass concentrations i cated that a large amount of inert organic ma exists in the attached growth reactor. REDUCTIONS OF ENTERIC MICROOR NISMS DURING AEROBIC SLUDGE DIG TION.

Cornell Univ., Ithaca, NY. Center for Envi mental Research.
J. H. Martin, H. E. Bostian, and G. Stern.
Water Research WATRAG, Vol. 24, No. 1 1377-1385, November 1990. 4 fig, 10 tab, 20
USEPA Cooperative Agreement CR-811776.

Descriptors: *Aerobic digestion, *Enteric bact *Enteroviruses, *Sludge digestion, *Wastew treatment, Coliforms, Comparison studies, F streptococci, Mathematical equations, Temp ture effects.

Seasonal variations in the reductions of total form, fecal streptococci and enterovirus den

iat occur during conventional aerobic sludge di-
estion in cold climates were characterized. In
ddition, the potential for reduction in the densities
f these four groups of enteric microorganisms in
old climates by simple modifications that increase
rocess temperature by reducing heat losses was
emonstrated. To obtain the data, two 32 cu m
erobic digesters located at a small municipal
astewater treatment plant were operated continu-
sly over a period of 20 months. One digester was
conventional digester while the other was de-
gned to minimize heat losses and thus, facilitate
toheating. When the results obtained during 11
parate periods of steady-state operation at mean
ixed liquor temperatures ranging from 8 to 40 C
d at residence times of 10, 15, and 20 days were
mbined for analysis, it was evident that signifi-
nt reductions in the densities of the four groups
enteric microorganisms were dependent on both
sidence time and temperature. Using the Arrhen-
equation, it was possible to describe mathemati-
lly the temperature dependence of the rate of
10 reduction in density of each of these four
oups of enteric microorganisms. The four mathe-
tical relationships developed provide a rational
sis to determine residence times necessary to
ieve desired levels of indicator organism and
erovirus reductions during aerobic sludge diges-
n at mixed liquor temperatures ranging from 8
40 C. (Author's abstract)

odel using bacteriophage MS2 for the calcula-
of the effective dose in u.v.-disinfection by
chromatic light from a medium pressure mer-
lamp was studied. The model was based on
-order inactivation kinetics, the u.v.-absorption
trum of MS2-RNA as the action spectrum and
bert-Beer's law for light absorption by the
ents. The u.v.-sensitivity of the phage was
rated with a low pressure mercury lamp; the
tivation rate constant (k) was 0.0106 sq m/J,
ch corresponded well with previously reported
. The model fitted actual data in most experi-
ts, although tailing effects were observed. In
e experiments a different value of k was neces-
to fit the actual inactivation curves, varying
een 0.0077 and 0.0121 sq m/J. The repeatabi-
of inactivation experiments with RNA-bacter-
ages appears to be good, which is an advan-
when proposing these organisms as biological
dards for calibration of u.v.-lamps and disinfec-
units. (Author's abstract)

nithermomechanical pulp (CTMP)
ewaters are treated anaerobically, in full scale
ations, in spite of the presence of inhibitory
ounds. These compounds have not been well identified nor placed in an order of priority in terms of inhibitions to anaerobic bacteria. Therefore, anaerobic toxicity assays (ATA) were used to quantify the relative toxicity of resin acids to the total toxicity in bleached CTMP (BCTMP) wastewater. A resin acid mixture was prepared that matched as closely as possible the mean resin acid composition reported in wastewater from the Quesnel River Pulp Co. on five separate occasions. A series of resin acid concentrations ranging from 20 to 700 mg/L were assayed during the ATA. Resin acids were partitioned between the soluble wastewater and the fiber fractions. Therefore fiber toxicity was also compared to raw BCTMP wastewater toxicity. Results indicated that anaerobic toxicity in BCTMP with fiber wastewater is partly soluble and partly fiber associated. The anaerobic toxicity that is removed with the fiber is methanol soluble. The bulk of the fiber which is not methanol soluble exhibited no toxicity to the anaerobic cultures used. Resin acids inhibit anaerobic activity but BCTMP wastewater toxicity to anaerobic bacteria can only be partially explained by the presence of resin acids. The possible synergistic effects that other compounds may have in conjunction with the resin acids in BCTMP with fiber wastewater toxicity could not be excluded. (White-Reimer-PTT)

PHOTOCATALYTIC DEGRADATION OF ORGANOPHOSPHOROUS INSECTICIDES IN AQUEOUS SEMICONDUCTOR SUSPENSIONS.
National Chemical Lab. for Industry, Yatabe (Japan).
K. Harada, T. Hisanaga, and K. Tanaka.
Water Research WATRAG, Vol. 24, No. 11, p 1415-1417, November 1990. 6 fig, 12 ref.

Descriptors: *Catalysts, *Insecticides, *Organophosphorus pesticides, *Photolysis, *Wastewater treatment, Chemical treatment, Degradation products, Degradation rates, Formaldehyde, Hydrogen peroxide, Photocatalytic degradation.

A method was sought to improve the efficiency of the photocatalytic process for the degradation of organic and inorganic substances in wastewater. Two organophosphorus insecticides, dimethyl-2,2-dichlorovinyl phosphate (DDVP) and dimethyl-2,2,2-trichloro-1-hydroxyethyl phosphonate (DEP), were degraded in the presence of suspended TiO2 by illumination with a super-high pressure mercury lamp or by exposure to sunlight. Pt-loading to TiO2 enhanced the degradation rates 4.5 for DDVP and 6-fold for DEP. The addition of H2O2 to the suspension also enhanced the rates 10-fold for DDVP and 2-fold for DEP. The final degradation products were Cl(-), PO4(3-), H(+) and CO2, and one of the intermediates was formaldehyde. (Author's abstract)

IONIC STRENGTH IN DEEP BED FILTRATION.
Asian Inst. of Tech., Bangkok (Thailand). Div. of Environmental Engineering.
J. S. Chang, and S. Vigneswaran.
Water Research WATRAG, Vol. 24, No. 11, p 1425-1430, November 1990. 4 fig, 3 tab, 15 ref.

Descriptors: *Deep bed filtration, *Filtration, *Ionic strength, *Ions, *Wastewater treatment, Conductance, Particulate matter, Removal efficiency, Sodium chloride, Zeta potential.

The removal efficiency of particles in deep bed filtration depends on both transport and attachment mechanisms of particles. The particle attachment mechanisms depend mainly on chemical characteristics of aqueous phase, suspended particles and filter media. Two different suspensions were used to study the effect of ionic strength on the particle removal efficiency. The ionic strength of suspension was varied by adding a known amount of sodium chloride. The removal efficiencies were related to ionic strength and zeta potential. Most of the suspended particles found in water and filter grain used in deep bed filtration carry negative charges which produce a repulsion force that can be measured in terms of the zeta potential. The zeta potential gets closer to zero the higher the filter removal efficiency. Two different zones were observed when the initial collection efficiency was platted against the concentration of electrolyte (ionic strength). For ionic strength lower than a certain value of NaCl concentration (in this study less than 0.219 mol/L), the variation of the initial collection efficiency was significant even for a small change in ionic strength; for ionic strength above this value the initial collection was constant. The clean filter bed efficiency and removal efficiency during the ripening period for various strengths were quantitatively related to the two model coefficients appearing in the O'Melia-Ali model. These model coefficients represent the filter medium-particle and particle-particle attachments. This type of quantification of the effect of ionic strength in terms of filter efficiency is very useful in filter design and operation control. (Author's abstract)

Descriptors: *Activated sludge process, *Environmental engineering, *Model studies, *Substrates, *Wastewater treatment, Aerated lagoons, Biomass, Computer programs, Differential equations, Model testing, Monod term, Numerical models.

In many engineering fields it is common practice to use simple models for design purposes. In environmental engineering it is customary to design biological treatment systems on the basis of steady-state reactor behavior, which is inadequate for the study of treatment systems under operational conditions. The description of transient behavior requiring the use of differential equations, as opposed to algebraic steady-state equations, increases the modeling effort substantially. A numerical technique for predicting the response of a completely mixed activated sludge system (with recycle) to transient substrate inputs has been developed. Substrate utilization and biomass growth were modeled by Monod kinetics. Computational efficiency is achieved by 'locally linearizing' the Monod expression, and by decoupling the two mass balances by assuming biomass to be constant locally over a time step. The subsequent solutions are simple and ideally suited for personal computers. Comparisons with numerical solutions of the complete equations show a high degree of accuracy and robustness for the proposed technique. (Author's abstract)

EFFECTS OF CHEMICAL PHOSPHORUS PRECIPITATION ON ANAEROBIC DIGESTION.
Imperial Coll. of Science and Technology, London (England). Dept. of Civil Engineering.
S. Yeoman, J. N. Lester, and R. Perry.
Environmental Technology (Letters) ETLEDB, Vol. 11, No. 8, p 709-720, 1990. 6 fig, 2 tab, 30 ref.

Descriptors: *Anaerobic digestion, *Biological wastewater treatment, *Chemical precipitation, *Phosphorus removal, *Sludge digestion, *Wastewater treatment, Activated sludge, Alkalinity, Alum sludge, Aluminum sulfate, Methane.

The use of chemicals such as aluminum sulfate and ferric chloride in biological wastewater treatment can achieve excellent phosphorus removals; however, it can also influence the process of anaerobic digestion. Results from the operation of laboratory scale anaerobic digesters using chemically precipitated sludges indicated that such treatment had detrimental effects on digester operation. A digester that only contained 25% precipitated activated sludge and the control were similar in terms of performance, because the sludge concentration was not high enough to affect performance signifi-

cantly. It was concluded that alum and ferric chloride used for the precipitation of phosphorus do adversely affect anaerobic digestion, especially in terms of methane production and alkalinity. However, this could be overcome if co-precipitation was used and the majority of sludge sent to anaerobic digestion (approximately 75% depending on works practice) is chemically untreated. (Fish-PTT)

Descriptors: *Activated sludge process, *Bacterial analysis, *Biomass, *Enzymes, *Wastewater treatment, Artificial substrates, Assay, Biodegradation, Fermentation.

To control biomass activity within any process (e.g. fermentation or activated sludge in wastewater treatment), it is necessary to choose enzymatic activities not only representative of the physiological state of the bacterial cells but also easy to measure. Phosphatase, glycosidase, and protease activities are possible candidates for this assay as they were shown to respond to environmental stress such as starvation or poisoning. Bacterial protease activity was assayed using L Leucine beta naphthylamide as artificial substrate. Apparent KM values ranging from 112 to 606 micromoles of substrate consumed/g of biomass (dry weight) were obtained with activated sludge samples. Specific activities were in the range from 7 to 26 micromoles of substrate consumed/min/g of sludge (dry weight). It was established that proteolytic activity from various bacterial populations can be conveniently measured at 30 C and pH 8.5. In these conditions, the substrate and product molecules of the protease assay are nonbiodegradable, nontoxic, and not significantly adsorbed by the biomass. (Author's abstract)

Sludge generated at recombinant DNA processing facilities consists mainly of biological solids such as cells and cell debris. The solid levels in the sludge samples can vary depending on the process used to concentrate solid materials. The solids content and physical properties of sludge will affect the selection of an appropriate decontamination agent. Potential techniques for sludge decontamination include incineration, thermal (dry-heat and steam) treatment, gamma and electron radiation, microwave radiation and chemical decontamination. Each of these techniques on microbial inactivation can be effective in the treatment of recombinant DNA sludge. However, the required dosage for each of these procedures needs to be established on a case-by-case basis. Depending on the sludge characteristics, volume and treatment cost, the need for pretreatment or combined treatments should also be evaluated. Since the verification of the extent of decontamination is extremely difficult with sludges, high safety factors should be incorporated during the design of treatment units and good maintenance and operating procedures employed. DECONTAMINATION TECHNOLOGIES FOR RELEASE FROM BIOPROCESSING FACILITIES: PART VI. VERIFICATION OF WASTEWATER DECONTAMINATION.
Battelle Memorial Inst., Columbus, OH. Environmental Science Dept.
G. B. Wickramanayake.
CRC Critical Reviews in Environmental Control CCECAU, Vol. 19, No. 6, p 539-555, 1990. 2 fig, 5 tab, 29 ref. EPA Contract No. 68-03-3248.

Descriptors: *DNA, *Decontamination, *Hazard assessment, *Microorganisms, *Pharmaceutical wastes, *Statistical analysis, *Sterilization, *Wastewater treatment, Effluent streams, Waste treatment.

Wastes generated in bioprocessing facilities can be decontaminated using chemical and physical agents commonly employed in wastewater disinfection and sterilization processes. The decontamination process involves inducing irreversible loss of viability to the organism and its subcellular components, such as genetic elements, if necessary. The extent of decontamination or the permissible levels of recombinant DNA microorganisms in the final effluent is governed by the acceptable risk associated with the organism of concern. For biological agents with a high degree of risk, sterility can be the targeted treatment end point. Because of the limitations associated with sampling and viability assessment techniques, the sterility of a waste stream cannot be absolutely verified. At best, the waste stream can be shown to contain less than a given number of microbes at a desired confidence limit. Binomial probabilities can be used to make statistical inferences from verification test results. Large sample sizes (total numbers of samples) are required to verify high levels of decontamination. Statistically, the total volume of the waste stream has little or no effect on the selection of sample size to determine a certain concentration of microorganisms. The frequency of conducting verification tests depends on the risk level associated with the organism and the variability of waste characteristics and operating parameters of the decontamination system. The validity of verification test results has a significant bearing on the viability-assessment method. Any concentration or recovery methods to improve the sensitivity of this technique should be employed with caution because such techniques can have adverse impacts in the accuracy of results. Because almost all of the detecting and monitoring techniques are based on the culturability of organisms, such in vitro tests have to be representative of the viability of the organism. If biological indicators are used to verify sterility, such organisms (1) need to be more resistant than the rDNA organism, (2) should be able to be detected at low concentration and (3) should not pose a health risk. A new wastewater treatment plant in St. Igna Michigan, was designed to provide low-co simple to operate, and not requiring advanc technical educational backgrounds for its pers nel to maintain it. This project was patterned af unique wastewater-disposal problems result from the area's fluctuating population and ha winters, while addressing concern for the are forests, wetlands, endangered species, high qua lake trout waters, and archaeological sites. T plant operates on a relatively simple aera lagoon process with gravity flow, which preclu the need for pumps. The wastewater treatm process involve surface aspirators using guideli developed for dual-power level lagoons in southeast USA. Effluent is detained for half a in a final polishing pond for additional clarifica before it is disinfected by UV. A cascade wate aerator raises the dissolved oxygen content of effluent before discharge to Lake Huron. The wastewater treatment plant was placed onlin June 1988, just before the July 1 deadline secondary treatment under the Clean Water From the outset, the plant met discharge limits secondary treatment set by the Michigan Dep ment of Natural Resources. However, operati problems related to the chemical feed system the phosphate removal process caused effl phosphorus levels to exceed the 1.0 mg/L limi a short period. Adjustments were successf made to correct this problem. (Medina-PTT)

Descriptors: *Administrative agencies, *Bo *Digested sludge, *Massachusetts, *Public opi *Sludge disposal, *State jurisdiction, *Waste facilities, Education, Legislation, Sludge s Tides.

Phasing out ocean disposal of wastewater sl and choosing alternate sites to dispose o sludge require cities to make unpleasant accor dations in solving this example of an environm problem. Such is the case in Northeastern c cities like Boston, Massachusetts. Twice dail gested sludge from the two primary treat plants serving Boston and 42 neighboring and towns is flushed into the shallow wate Boston Harbor on the outgoing tides. Stud the early 1970s concluded that 25-30% o discharge solids return and settle out in the h floor. Since that time, several plans were oped for sludge disposal by other means, but were implemented because the public and re tory agencies did not support the recomm technology or the siting choice. Finally, court pressure, the state legislature in early formed the Massachusetts Water Resource thority (MWRA) to take charge of the h cleanup. Studies made by this agency ind that the most effective tool for educatin public about sludge management technolog information about similar systems in other co nities and how it would apply to the local tion. Also, after weighing public comment MWRA enhanced its credibility and public

y dealing decisively on ruling out incineration, in
ite of regulatory pressure for continued contin-
ency planning, and agreeing to drop composting
favor of another reuse technology with better
dor control in spite of potentially higher cost.

ts, *Soil chemistry, Heavy metals, Metals, Path
ollutants, Seasonal variation, Sludge drying,
city, Trace elements.

e rates of dried sewage sludge (22.5, 45.0, and
megag/ha) were applied to a degraded semi-
grassland site on the Upper Rio Puerco Wa-
ed in west-central New Mexico. Various soil
plant parameters were determined over four
ing seasons. Most soil macronutrients, such as
gen, phosphorus, and potassium, and micronu-
ts, such as copper, iron, manganese, and zinc,
ased linearly with increasing sludge amend-
rates. Heavy metals (cadmium and lead) did not change as a result of sludge amendment in the first three growing seasons. However, concentrations of soil copper, manganese, and cadmium were just above maximum acceptable standards in the heaviest sludge treatment after four growing seasons. Plant density, species richness, and diversity all decreased with increasing sludge rates. However, total plant foliar cover and herbaceous yields increased significantly with the application of sludge. Blue grama (Bouteloua gracilis (H.B.K.) Lag.) cover and yields, in particular, increased twofold to threefold over the control as a result of sludge amendment, whereas broom snakeweed (Gutierrezia sarothrae (Pursh) Britt. + Rusby) density decreased over four growing seasons. The most favorable soil and vegetation results were from the 22.5 and the 45 megag/ha sludge application rates. The near complete elimination of snakeweed after four growing seasons and the increase in blue grama cover and production as a result of sludge amendment may help to control and/or hinder the reestablishment of snakeweed plants. This study showed that sewage sludge from a nonindustrial city such as Albuquerque can be safely applied to a degraded grassland in the semi-arid Southwest without any apparent adverse environmental effects at sludge rates up to 45 megag/ha. TRACE METAL ANALYSIS OF SEWAGE SLUDGE AND SOILS IN BAHRAIN.
Bahrain Univ., Manama. Dept. of Chemistry.
M. S. Akhter.
Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 147-152, May 1990. 2 tab, 16 ref.

Descriptors: *Bahrain, *Heavy metals, *Land disposal, *Path of pollutants, *Sludge analysis, *Sludge disposal, *Trace metals, Agriculture, Soil amendments, Soil chemistry, Soil contamination, Toxicity.

Trace metals such as lead, zinc, copper, nickel, cadmium, and iron were determined in sewage sludge produced at a sewage treatment plant in Bahrain (Tubli) and soils. The soils, both untreated and treated with the sludge are used for agricultural purposes in Bahrain. The trace metal levels showed the following range (microg/g dry weight): lead, 242 to 609; zinc, 704 to 836; copper, 329 to 512; nickel, 23 to 41; cadmium, 1.8 to 3.9; and iron, 1867 to 4824. The data show the degree to which untreated soils have already been contaminated with trace elements. The level of trace elements found in sludge showed the following range (microg/g dry weight): lead, 140 to 186; zinc, 597 to 836; copper, 348 to 449; nickel, 47 to 53; cadmium, 5.7 to 9.2; and iron, 5950 to 8520. Mean levels were generally close or lower than mean concentrations reported in the United Kingdom and the United States for sludge. They were also lower than the suggested concentration limits for application of sludge on agricultural land, which is one of the most cost-effective and attractive techniques for sludge disposal. Soils treated with this sludge (after 1 year) were also analyzed and showed substantial enhancement of the available level of trace elements in the soil. This enrichment will eventually lead to an increase in the trace element level in plants grown for human or animal consumption, with potential phytotoxic effects, and the possibility of toxic effects on livestock and human beings. EFFECT OF SOLID-PHASE SPECIATION ON METAL MOBILITY AND PHYTOAVAILABILITY IN SLUDGE-AMENDED SOIL.
Instytut Uprawy, Nawozenia i Gleboznawstwa, Pulawy (Poland). Trace Element Lab.
S. Dudka, and A. Chlopecka.
Water, Air and Soil Pollution WAPLAC, Vol. 51, No. 1/2, p 153-160, May 1990. 8 tab, 16 ref.

Descriptors: *Bioavailability, *Land disposal, *Path of pollutants, *Sludge disposal, *Soil amendments, *Speciation, *Trace metals, Adsorption, Agriculture, Leaching, Lysimeters, Plant physiology, Sequential extraction.

In land application of sewage sludge large amounts of trace metals may be introduced into the soil. In addition, contamination of groundwater with trace metals is likely to occur following massive sewage sludge application to the land. Sequential extraction was utilized for partitioning cadmium, chromium, nickel, and zinc, in soil and sludge samples, into five operationally-defined fractions: exchangeable, bound to carbonates, bound to iron-manganese oxides, bound to organic matter, and residuals. The highest amount of cadmium, nickel, and zinc, expressed as percent of the total, were found in the iron-manganese oxide fraction of the sewage sludge. Chromium was significantly associated with the organic fraction of the sludge. The residue was the most abundant fraction for all metals studied in the untreated soil, and for cadmium and nickel in the sludge-treated soil. The concentration of exchangeable cadmium and chromium was relatively low in the untreated soil and did not change much after sludge application, whereas the concentrations of exchangeable zinc increased about 50 times and the concentrations of exchangeable nickel doubled in the sludge-treated soil. A lysimetric experiment revealed an increase in zinc and nickel uptake by ryegrass and in the percentage of metals leached from the soil profile after massive sludge application. In contrast, only negligible changes were observed for cadmium and chromium. The assumption that mobility and biological availability are related to metal speciation was confirmed by the agreement between the distribution pattern of cadmium, chromium, nickel and zinc in the soils, the uptake of the metals by plants and their capacity for leaching out from the soils. GUIDELINES AND INTEGRATED MEASURES FOR PUBLIC HEALTH PROTECTION IN AGRICULTURAL REUSE SYSTEMS.
World Health Organization, Geneva (Switzerland). Div. of Environmental Health.
I. Hespanhol.
Aqua AQUAAA, Vol. 39, No. 4, p 237-249, August 1990. 5 fig, 8 tab, 22 ref.

Descriptors: *Public health, *Wastewater disposal, *Wastewater farming, *Wastewater irrigation, *Wastewater utilization, *Water reuse, Agriculture, Coliforms, Epidemiology, Helminths, Pathogenic bacteria, Pathogens, Population exposure, Sanitary wastewater.

Wastewater recycling through agricultural schemes should be considered the preferred method of disposal and treated as an integral part of water resources planning. Based on a theoretical model predicting a descending order of risks of pathogen transmission by irrigation with raw wastewater, and on extensive epidemiological research done in the past 15 years, a new microbiological quality guideline in terms of concentration of intestinal nematodes and fecal coliforms is appropriate. The actual risk of irrigation with treated wastewater is much lower than previously estimated, and the early microbial standards and guidelines for effluent reuse were unjustifiably restrictive, particularly with respect to bacterial pathogens. Public health protection of the exposed groups can be attained through integrated measures which include wastewater treatment, crop selection, appropriate wastewater application, and human exposure control. Appropriate technical and institutional measures to provide complete protection to both workers and consumers depends upon the availability of resources (institution, staff, funds), existing social and agricultural practices, and existing patterns of excreta-related diseases. Topics for additional research include wastewater quality assessment, treatment technology, applica-

tion technology, human exposure control, sociocultural research and integration measures, epidemiological research, and aquaculture research. (Tappert-PTT)

Research has demonstrated the usefulness of the Microtox bioassay in assessing the acute toxicity of organic compounds. Recently, the use of the Microtox bioassay has been extended to applications in hazardous waste management. The rapidity of the test, low sample requirements, and low cost provide several advantages over chemical analysis, especially for complex waste mixtures. Microtox bioassay results correlate closely with results from rainbow trout bioassays, and are more sensitive to inhibitory chemicals than activated sludge organisms. An experimental approach using batch reactors and soil columns was implemented in the laboratory to evaluate the detoxification and mobility of a toxic complex hazardous waste (a composite of three types of petroleum refinery wastes including American Petroleum Institute separator sludge, dissolved air flotation float, and slop oil emulsion solids) in soil. The objective of the study was to quantify the extent and rate of detoxification of a complex hazardous waste as affected by soil type and waste application rate. The extent and rate of detoxification was directly related to waste loading rate for both soil types (Kidman sandy loam and Nunn clay loam) investigated, in both batch reactors and soil column reactors. Analysis of the toxicity of aqueous soil extracts at incremental depths through soil columns and of soil column leachate indicated a low leaching potential for the complex petroleum refinery waste. SITING CONSIDERATIONS FOR RESOURCE RECOVERY FACILITIES.
STV, Inc., Pottstown, PA.
R. Zyma.
Public Works PUWOAH, Vol. 121, No. 10, p 84-86, 134, September 1990. 1 fig.

Descriptors: *Administrative agencies, *Resource recovery facilities, *Site selection, *Waste disposal, *Waste recovery, Economic aspects, Environmental assessment, Environmental impact, Political aspects, Resources management.

The siting of resource recovery facilities is a complicated and often time-consuming procedure. The process must withstand the significant and somewhat relentless scrutiny of the public, regulatory agencies, and other interested parties. Even upon completion of the siting process, the regulatory agency permitting process remains a major obstacle. There are many technical, financial, environmental, and political considerations in selecting resource recovery as the study area's solid waste disposal option. Selecting a site that has a reasonable chance of withstanding these pressures is the initial step toward a successful project. Steps for resource recovery site selection start with determining the siting objectives and the study area. After selecting siting criteria, how to utilize that criteria must be established. Regional screening will identify candidate areas which must be narrowed into a few preferred areas. Selected sites within those areas should be rated and ranked. Environmental assessments will be needed for the highest ranked sites. After a preferred site is selected, preliminary design and the process of gaining regulatory and public approval can begin. Since around 1970, scientific research has been conducted to assess the benefits and risks of using municipal sewage sludge on cropland. One of the most important findings of sludge research is that certain sludges have a 'no observed adverse effect level'. Much work has shown that sludges can be beneficial. No observed adverse effect level sludges, however, have especially low risk. The adsorption of metals and organics by adsorption sites in sludges is the technical reason why equal amounts of metals or organics can be applied in no observed adverse effect level sludges without effects, while additions of pure chemicals to soils can cause adverse effects. The 'Soil-Plant Barrier' concept considers the potential toxicity to the food chain if trace elements are applied to soils. Some metals are so insoluble or so strongly adsorbed to soil or in plant roots that they are not translocated into edible plant parts. Other elements are taken up by plants from sludge treated soils to a level that they may reduce the yield or even kill crops. Because of this phytotoxicity, excessive plant uptake compared to levels tolerated by animals, is prevented, thus protecting the food chain. Exceptions to the Soil-Plant Barrier exist: livestock have been injured by excessive selenium and molybdenum and humans have been injured by cadmium. Sludge utilization was first regulated in 1979. The EPA has developed 12 fundamental pathways for risk assessment. The highest possible exposure to sludge applied contaminants can be avoided by using subsurface injection equipment or mixing the sludge into the plow layer soil before the grazing crop is seeded. Hazardous and radioactive wastes created in uranium mining and milling are often stabilized from erosion by placing a protective filter blanket and armor riprap layer over a thick earth cover. Models developed for the transient routing of intense rainfall on these small armored slopes depend on expressions for flow resistance below and above the surface of the armored layer. A series of experiments was conducted in two flumes to collect data on the basic relationships of flow resistance. Crushed rock of 26-155 mm median diameter was placed on embankments with slopes ranging from 0.01 to 0.2 and subjected to steady flow in the flumes. Flow through the rock layer was approximately proportional to the rock-layer porosity, the square root of the slope, and the mean diameter of the rock, and weakly proportional to the stage. The portion of flow through the filter layer generally cannot be neglected. Flow resistance decreased and conveyance greatly increased when the stage exceeded the depth of the rock layer. A model for flow both beneath and above the rock surface on an armored slope was synthesized from formulas developed for flow in rubble dams and Darcy-Weisbach formulas developed for flow in gravel bed streams and mountain rivers. The results of the model compare favorably to the experimental flow measurements. (Author's abstract)

Descriptors: *Animal feed, *Food processing industry, *Industrial wastes, *Pollutant identification, *Priority pollutants, *Sludge analysis, Food processing wastes, Metals, Pathogens, Pesticides, Sludge disposal, Sludge utilization.

A long-term, comprehensive study was conducted to determine the safety and efficacy of food processing sludges when used as an animal feed supplement. Sixteen different food processing plants were sampled and their sludges analyzed for 144 different compounds and elements, including those on EPA's list of priority pollutants. All sludges were found to have high protein and nutritive value while having low priority pollutant concentrati

one of the recommended limits for minerals in imal diets would be exceeded when fed at the commended 10% level. The variability in sludge mposition over time was studied at one plant for o years and found to be low (less than 30%). en though there exists a variability in the major d trace elements between the different types of od processing industries and each will have to be aluated separately, all of the facilities using bio- gical treatment have one thing in common; the mass (sludge) produced has a high nutritive ue while being low in priority pollutants. Food ocessing sludges need can be excellent sources of mal feed and need to be better used. (Author's tract)

scriptors: *Energy costs, *Incineration, *Municipal wastes, *Sludge disposal, *Waste management, astewater treatment, Performance evaluation, dge treatment.

dge handling and disposal have become major rational concerns at many wastewater treatt facilities. Today there is renewed interest in ge incineration. There is an increased need for duals volume reduction, and technical improvets have occurred in the fields of energy recov- sludge thickening and dewatering and emis- s control. A study was performed to evaluate status of sludge incineration with low fuel use. ee of the facilities selected for the study used tiple-hearth technology and one facility used lized-bed technology. Raw data were obtained ugh a review of available plant records and ussions with each plant's staff. Both energy t and output were estimated for each unit ess, and energy efficiency was examined on ral levels. For a fuel efficient sludge incinerr facility, the study found that annual auxiliary consumption within the furnace should be in range of 1.2 to 1.4 mil kJ/dry tonne (1.0 to 1.2 Btu/dry ton) of sludge cake processed. Total al costs for the incineration system after dewag should be in the range of $180 to $225/dry e ($163 to $204/dry ton) of sludge cake proc- d when operating at capacity. The design, opon, and managerial features that strongly conte to energy-efficient sludge incineration in- e: a uniform furnace feed rate and quality; staff ing and motivation, and cooperation between oyees; a strong equipment maintenance pro- ; a common staff goal of energy efficient ce operation; and installation of a common ating philosophy and guidelines for the entire (VerNooy-PTT)

riptors: *Dredging wastes, *Mobile Bay, rflow, *Waste disposal, Alabama, Dredging, tests, Slurries, Solids.

orizing legislation for the deepening of navi- channels in Mobile Bay specifies that the new work dredged material and material from future maintenance dredging must be placed in an approved open-water disposal site in the Gulf of Mexico. Large mechanical dredges with clamshell buckets are being used for the new work dredging. Hopper barges are loaded with the dredged material and transported by tug to the disposal site. Mechanical dredging is also the most likely technique for future maintenance. The economic loading of the hopper barges and the potential environmental impact associated with barge overflow during loading are important issues. Therefore, a field study was conducted to give site-specific information on the loading gains achieved by overflow, and the characteristics of the overflow for conditions in the Mobile Bay. The field study included: data collection on dredge-operating characteristics; sampling and testing of material comprising the barge overflow; and monitoring the loading characteristics of the barges. The dredge CHICAGO (equipped with a 30 cu yd clamshell bucket) and 6000 cu yd hopper barges were used during the study. Loads gained during three overflow tests were 4.1, 1.2, and 11.5% for overflow periods of 60, 24, and 65 minutes. For all three overflow tests, the overflow ended with a significant amount of diluted slurry ponded in the barges, indicating that additional load gains would be possible with prolonged periods of overflow. The solid concentrations of bucket material samples averaged 1,080 g/L, while the overflow was essentially constant for the entire period of overflow, and averaged 80 g/L. Results indicate that retention of solids in the hopper barges occurs during the overflow process for mechanical dredging. (Author's abstract)

ASSESSMENT OF OCEAN WASTE DISPOSAL. TASK 5. HUMAN HEALTH IMPACTS OF WASTE CONSTITUENTS. II. PATHOGENS AND ANTIBIOTIC-AND HEAVY METAL-RESISTANT BACTERIA.
Maryland Univ., College Park. Dept. of Microbiology.
D. J. Grimes.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-153084. Price codes: A08 in paper copy, A01 in microfiche. May 1986. 132 p, 11 fig, 27 tab, 283 ref.

Descriptors: *Human diseases, *Ocean dumping, *Public health, *Waste disposal, *Wastewater pollution, *Water pollution effects, Coastal waters, Estuaries, Pathogenic bacteria, Waste management, Water pollution control.

The disposal of wastes in the ocean has been practiced by coastal nations for decades. All areas of the ocean have been subject to disposal use, including estuaries, nearshore, open shelf, and deep ocean sites. Until recently it was believed that pathogenic bacteria did not survive for any significant period of time in estuarine and marine environments. This document provides a description of: potentially harmful constituents of wastes (viruses, pathogenic bacteria, pathogenic fungi, pathogenic algae, protozoa, and helminths); ways in which these constituents could reach humans; known incidents of human disease contracted from wastes; detection of waste-borne disease agents; management technologies (facultative lagoon systems, activated sludge treatment systems, trickling-filter treatment systems, and disinfection); and monitoring and predictive trends. SUMMARY OF RISK ASSESSMENT METHODOLOGIES FOR MUNICIPAL SLUDGE REUSE OR DISPOSAL OPTIONS.
Environmental Protection Agency, Cincinnati, OH. Office of Research and Development.
R. J. F. Bruins, L. Fradkin, and J. F. Stara.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-218168. Price codes: AO2 in paper copy, AO1 in microfiche. Report No. EPA/600/D-89/016. 1989. 7p, 13 ref.

Descriptors: *Path of pollutants, *Risk assessment, *Sludge disposal, Air pollution, Food chains, Groundwater pollution, Landfills, Leachates, Management practices, Municipal wastewater, Ocean disposal.

Risk assessment methods have been developed which can be used to calculate criteria for controlling toxic pollutants in municipal wastewater sludges. These methods consist of algorithms, ranging from simple to complex, which allow calculation of exposure and risk from various sludge disposal practices. These calculations may show a need for management practice controls or for numerical limits on specific pollutants. Criteria for land-applied or distributed and marketed sludge may take the form of application rate limits (kg/ha) or concentration limits, calculated to control pollutant levels in the food chain or off-site movement in air or water. Criteria for landfilled sludge are defined in terms of acceptable leachate concentrations, as determined by an appropriate leachate characterization test, to prevent excessive groundwater contamination of vapor emission. Incineration criteria are expressed as limitations on stack emission rates (g/sec), based on predicted air concentrations at ground level. Criteria for sludge which is ocean-disposed at the 106-Mile Site are calculated in terms of sludge concentration and total daily pollutant input to the site, in order to protect marine life and human consumers of seafood. These risk assessment methods were developed in a research environment in order to promote scientific consistency in the regulatory process. (Author's abstract)

HAZARDOUS WASTE CONTAINMENT USING CLAY LINERS.
Wayne State Univ., Detroit, MI. Dept. of Civil Engineering.
C. J. Miller, and M. Mishra.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 191-199, 4 fig, 12 ref.

Descriptors: *Clay liners, *Groundwater pollution, *Groundwater quality, *Hazardous waste disposal, *Landfills, *Leaching, *Path of pollutants, *Water pollution control, *Water quality management, Darcys law, Drying, Flow models, Groundwater management, Landfill liners, Leakage, Mathematical analysis, Model studies, Open-channel flow, Porosity, Vertical flow, Water resources management.

The use of clay liners is prevalent in the waste disposal industry. The liner is expected to perform a most critical function. It provides a barrier between the natural environment and the deposited waste. It is obvious that unrestricted migration of the waste could lead to soil, groundwater, and

surface water contamination. However, it has also become evident that such environmental problems are also prevalent in the vicinity of landfills constructed with clay and/or synthetic liner barriers. Current models have been shown to underestimate the actual leakage volumes because of the existence of macropores, especially attributed to desiccation cracking. A conceptual model of flow through cover liners has been developed that acknowledges the existence of macropores. Flow through the clay matrix is modeled using Darcy's law, while the macropore flow component is modeled using the equations governing analogous processes in open channel and closed conduit hydraulics. These equations are well developed and verified in other applications. Future investigations will provide the complete mathematical model of flow through clay liners incorporating the macropore concepts. Collection of field data for verification of the model is underway. (See also W91-02672) (Fish-PTT)

SLUDGE DISPOSAL STRATEGY FOR DUMFRIES AND GALLOWAY REGIONAL COUNCIL.
J. N. Dobson.
Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 4, No. 4, p 371-378, August 1990. 3 fig, 9 tab, 7 ref.

Descriptors: *Land disposal, *Legislation, *Scotland, *Sludge disposal, *Waste disposal, Agriculture, Dumfries, Galloway, Odor control, Regulations, Septic tanks, Sludge lagoons, Sludge treatment, Waste management.

The Dumfries and Galloway Regional Council's largely rural statutory area extends to 6370 sq km, with a population of 146,000. During 1988, the Council, mindful of impending legislation likely to affect existing sludge disposal outlets, particularly those in agricultural land, commissioned a detailed study into all aspects of sewage sludge production, treatment, storage and disposal. The aim of the study was the production of a regional sludge disposal strategy. Consideration was given to five different options of sludge disposal. The following recommendations were outlined: (1) disposal of sewage sludge to agricultural land; (2) the Regional Council to carry out spreading operations; (3) retain lagoons as emergency reservoir storage; (4) construction of four sludge treatment centers, incorporating mesophilic anaerobic digestion and fine screening; (5) install an odor control plant; (6) operate a microcomputerized sludge maintenance control system; (7) appoint a sludge management officer; (8) purchase and operate farms; (9) utilize the expertise of the Barony College of Agriculture; (10) commission a study to identify an optimum working plan for sludge tanking operations; (11) rationalize the sizes of community septic tanks; (12) improve sludge thickening at larger works; (13) develop a program for emptying community and private septic tanks; (14) intensify trade effluent monitoring; and (15) terminate centrifuge dewatering and thermophilic aerobic digestion of sludge at Annan. Descriptors: *Fracture permeability, *Gas migration, *Geologic fractures, *Path of pollutants, *Radioactive waste disposal, *Underground waste disposal, Boundary conditions, Flow rates, Mathematical models, Permeability, Pressure distribution.

A mathematical model is presented for the upward pulsating gas-water displacement, from a gas source at a constant production rate or pressure at the bottom boundary to a constant pressure boundary at the top boundary. The study shows a complicated flow phenomenon caused by the unequal advance of the gas in fractures of different permeability or different inclinations. The results show that the gas breakthrough at the surface is governed by the high permeability factor. At a constant rate of gas production the breakthrough is associated with a gas pressure build up and reinitiates the upward displacement. Calculations with average properties of the fracture permeability, using the continuum approach, will underestimate the breakthrough time of the gas at the surface. Under the constant pressure boundary conditions at the top of the cavern the average permeability will overestimate the amount of gas carried out by the fracture network. Under constant flow rate boundary conditions at the top of the cavern, calculations with average fracture permeability will overestimate the pressure in the cavern. The problem is of practical interest for low-level radioactive waste repositories located in hard rock below the sea bottom. (Author's abstract)

DIVERSION CAPACITY OF CAPILLARY BARRIERS.
Disposal Safety, Inc., Washington, DC.
B. Ross.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2625-2629, October 1990. 2 fig, 7 ref.

Descriptors: *Capillary water, *Groundwater barriers, *Toxic wastes, *Waste disposal, *Water pollution control, Diversion structures, Hydraulic conductivity, Infiltration, Percolation, Permeability, Pressure potential, Soil porosity, Soil properties, Soil saturation, Waste management.

An important objective in the management of toxic wastes is to minimize the amount of water percolating through the wastes. An arrangement of unsaturated fine-grained soil overlying unsaturated coarse-grained soil along a sloping contact can, under appropriate circumstances, divert infiltrating water away from the coarser material. Such an arrangement is called a capillary barrier. The water is diverted by a capillary barrier flows downdip above the contact. The volume of water moving laterally increases in the downdip direction as additional infiltration is diverted by the barrier. Sufficiently far downdip, the laterally moving water wets the contact to the point that an amount of water equal to the infiltration flows downward through the coarse soil. The lateral flow at such a point represents the diversion capacity of the capillary barrier because this flow will not increase farther downdip. If the width (measured in the direction of dip) of the system is large enough that total infiltration exceeds the diversion capacity, the downdip portion of the barrier will not be effective. The diversion capacity can b calculated exactly in the quasi-linear approxima tion where the relationship between relative pe meability (k-rel) and pressure potential (psi) take the form k-rel = e to the alpha psi power. Th calculation shows that an upper bound on th width of capillary barriers is K-s tan phi/(q alpha), where K-s is the saturated hydraulic co ductivity of the fine soil, phi is the dip angle of th contact, and q is the infiltration rate. Large quantities of tailings are produced daily mining processes. Proper tailings disposal and m agement of tailings ponds are required for envir mental and economical reasons. Hydraulic me ods, in which tailings and water are mixed to fo a slurry, are often employed to transport tailin from the producing plant to the disposal s When the slurry is discharged into the tailin pond, the coarse solids settle out, forming a bea while the fine solids and water end up in tailings pond as sludge, which has to be sto permanently. The management of hydraulica deposited tailings is an important component c mining operation, and involves prediction of beach profile formed by the coarse solids. Tr sient beach profiles in tailings disposal were in tigated both experimentally and theoretically. effects of feed solids concentration and total slu discharge on beach profiles were examined usir plexiglass flume. It was found that the slope of beach and the rising rate of the beach at the so feeding point were much influenced by feed so concentration. On the other hand, when the f solids concentration is constant and the total slu discharge is varied, the slope of the beach does change significantly. A nonlinear mathemat model is developed to predict beach profiles. resulting partial differential equation is solved merically by a simple explicit scheme. Very g agreement between the experimental data and theoretical prediction is observed. The experin tal data are also correlated successfully wit power expression, which is often seen in mi engineering literature. (Author's abstract)

ABSENCE OF CADMIUM IN THE BLOOD HORSES FED OATS GROWN ON MUNICI SLUDGE-AMENDED SOIL.
G. A. Maylin, C. A. Bache, and D. J. Lisk.
Science of the Total Environment STENDL, 96, No. 3, p 313-316, August 1990. 2 tab, 10

Descriptors: *Blood, *Cadmium, *Oats, *Pat pollutants, *Sludge disposal, *Sludge utiliza *Water pollution effects, Farms, Food chains dustrial wastes, Municipal wastes, Toxicity.

Effluents from a number of industries whicl typically treated in municipal sewage plants r in cadmium-containing sludge. Disposal of sewage sludge by application to agricultural can result in uptake of cadmium by crops. were grown on soils which had been ame with sewage sludge from Syracuse, New The cadmium concentration in the sludge-g oats was 1.79 ppm dry weight. Horses were fe sludge-grown oats for 6 weeks during which blood samples were taken for the determinati cadmium. No significant differences were fou the concentration of cadmium in the blood horses consuming the oats compared with th

ıe blood before feeding began (control). The ell-known efficient accumulation of renal cadmi- n by horses may account for a lack of significant- increased cadmium in blood during the feeding eriod. (Author's abstract)

escriptors: *Glacial drift, *Hydraulic conductivi- *Landfill linings, *Leachates, *Permeability, mectitic till, Canada, Clay minerals.

ı evaluation is presented on the effects of leach- on the hydraulic conductivity, k, of a smectitic cial till used in the construction of a compacted rth liner for a landfill near the city of Saskatoon, skatchewan, Canada. Low gradient triaxial per- ability testing of the water-molded till over a 7- nth period with six pore volumes of test leach- at a hydraulic gradient of approximately 100 ve a hydraulic conductivity of 0.3 nm/s, com- red with 0.6 nm/s for the water-permeated nple at the same gradient. The k was also evalu- d at gradients of 20 and 50 during water perme- on and found to be 0.8 and 0.68 ncm/s, respec- ely. The slight decrease in k with increase in dient was attributed to a decrease in void ratio, ulting from a net increase in applied effective ess at the outflow end of the specimen. An essment of the clay mineral composition of the at the end of permeability testing did not show lapse of the smectite peak. Instead, the leachate peared to have actually enhanced the smectite k relative to the illite peak. It was concluded t the leachate did not have any detrimental act on the till and that the hydraulic conductiv- of the 0.3m thick liner underlying the landfill y not be expected to increase as a result of raction with leachate. gher state regulations on sludge management ermont compelled Environmental Conserva- municipal officials in 1987 to study and evalu- options for regional sludge management. The ons involved as many communities as possible allowed those generating the least sludge to efit from the economy of scale. This study lted in two conclusions. First, land application ewatered sludge cake (20% solids) represented gnificant savings over land application of liquid ge, because of the additional storage and trans- ation needs associated with land application of d sludge. Second, with the exception of the application of liquid sludge and vertical plug composting, the present worth costs of the aining alternatives are relatively close, ranging n $8.9 million for contract land application of atered sludge to $10.3 million for horizontal ted bin composting. The analysis for the Rut- land and Connecticut River Valley regions yielded similar results. Recommendations are given for the most cost-effective sludge management for each region studied. MICROBIAL QUALITY OF THE WATER IN THE DISTRIBUTION SYSTEM OF FLORENCE.
Florence Univ. (Italy). Inst. of Hygiene.
L. Gambassini, C. Sacco, E. Lanciotti, D. Burrini, and O. Griffini.
Aqua AQUAAA, Vol. 39, No. 4, p 258-264, August 1990. 1 fig, 3 tab, 27 ref.

Descriptors: *Florence, *Italy, *Pathogenic bacteria, *Pathogens, *Water distribution, *Water quality, *Water treatment, Bacteria, Pollutant identification, Potable water, Staphylococcus, Surface water, Water conveyance, Water quality monitoring, Water sampling, Water supply.

A significant tract of the water distribution network of the Florence waterworks, which purifies surface water from the Arno River, was monitored between March 1987 and February 1988. Physiochemical and microbiological parameters were analyzed in 66 samples of water. Samples were collected at 3-4 week intervals at six different points along the water distribution network. The network sampling points selected were used in an effort to establish the real residence time of water in the system. It was found that bacterial growth values were constant with the exception of a point at the end of the network, which experienced a lowering of chlorine and temperature variation. The most commonly isolated bacteria belonged to the families Pseudomonadaceae, Bacillaceae, Micrococcaceae, and Enterobacteriaceae as found by other authors. Staphylococcus hominis, S. warneri, Pseudomonas maltophila, and Bacillus spp. were commonly found in the network. Opportunistic pathogens such as S. aureus and P. aeruginosa occurred only once in particularly favorable conditions at the terminal point of the network. The adoption of water filtration through granular activated carbon, which is in process in the treatment plant for the surface Arno River water, will further improve the quality of distributed drinking water by reducing the biodegradable organic carbon levels and limiting the growth of microorganisms. EFFECT OF CHARGE DENSITY AND MOLECULAR MASS OF CATIONIC POLYMERS ON FLOCCULATION KINETICS IN AQUEOUS SOLUTION.
University Coll., London (England). Dept. of Civil Engineering.
J. Gregory, and S. Y. Lee.
Aqua AQUAAA, Vol. 39, No. 4, p 265-274, August 1990. 9 fig, 2 tab, 19 ref.

Descriptors: *Chemical coagulation, *Flocculation, *Polymers, *Suspension, *Water treatment, Cations, Physicochemical properties, Reagents, Silica.

At present there is limited understanding of dynamic aspects of polymer adsorption and flocculation, especially in agitated suspensions. Kinetic aspects of polymer adsorption and flocculation in stirred suspensions of silica particles have been studied using cationic polymers of different charge density and molecular mass. Silica particles were dispersed in deionized water and fractionated by sedimentation to give particles mainly in the 1-3 micrometer range. The polymeric flocculants were all copolymers of acrylamide or dimethylaminoethyl acrylate (DMAEA). The molar proportion of DMAEA determines the charge density. An optical method using a photometric dispersion analyzer was used to monitor flocculation. The results show that the rate of polymer adsorption can be slow compared to particle collision rate, especially when the polymer is of low charge density and low molecular mass. The charge density of a polymer is important in determining the optimum dosage. For all of the polymers used, the amount of positive charge adsorbed at their respective optimum dosages is about the same. However, the rate of adsorption and the flocculation rate may be affected by charge density and molecular mass. (Tappert-PTT)

IMPACT OF HANDPUMP CORROSION ON WATER QUALITY.
International Bank for Reconstruction and Development, Abidjan (Ivory Coast). Regional Water and Sanitation Group.
O. Langenegger.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 594-604, 7 fig, 1 tab, 2 ref.

Descriptors: *Corrosion, *Domestic water, *Groundwater quality, *Pumps, *Wells, *West Africa, Biofilms, Deterioration, Developing countries, Galvanized metal, Ghana, Iron, Ivory Coast, Pipes, Rural areas, Steel, Water mains.

The exploitation of groundwater by means of boreholes for supplying small user groups and rural communities with water has been widely applied in various parts of the world for decades. In recent years this practice has become global, with hundreds of thousands of boreholes drilled to tap low-yielding aquifers. In developing countries handpumps usually are used for lifting the water, although solar or other systems with submersible pumps also are used. The experience gained with handpump-equipped boreholes within the World Bank executed inter-regional UNDP-Handpumps Project (INT/81/026) provided quantitative data on the water quality of wells in terms of iron concentration and other parameters. The corrosive attack on galvanized iron, the effect of biofilms on the corrosion rate, and the difference between internal and external corrosion of rising mains are shown by these data. A biofilm developed on a mild steel specimen at 27 C within about 30 to 40 hr, whereas no biofilm, or only traces, was observed on the specimen at 10 C. The dissolution of iron through corrosion measured as iron increase

(total Fe) was indirectly proportional to the formation of the biofilm and the NH4 concentration at 27 C. The iron increase was higher and relatively constant at 10 C. Under prevailing conditions in the investigated areas (Ivory Coast and Ghana), galvanization does not protect mild steel from corrosion. Internal parts of rising main assemblies seemed to show a higher tendency to form protective biofilms compared to the external parts. The less a pump is operated, the more corrosion products are formed and accumulated in the rising main assembly and in the well. (See also W91-02288) (Rochester-PTT)

PULSA SOLAR: SOLAR WATER OSCILLATION PUMPS FOR VILLAGE HYDRAULICS.
Fluxinos Italia S.R.L., Grosseto.
T. E. Manning, E. Mencarelli, and G. Cefis.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 712-721.

Descriptors: *Developing countries, *Pumps, *Rural areas, *Solar energy, *Water supply, Africa, Cost analysis, Design criteria, Drinking water, Economic aspects, Oscillation pumps, Pulsa Solar, Semiarid lands, Wells.

A solar water oscillation pump (PULSA SOLAR) for village hydraulics in developing countries was developed that will supply 25 liters of water per person per day from boreholes with water depths of 0-50 m. The pump is designed to provide the minimum water prescribed by the World Health Organization for villages of 200 people for drinking and personal use. Photovoltaic arrays of only 160-240 Wp are employed. Analysis of the cost effectiveness of the PULSA system hand pumps compared to PULSA SOLAR pumps was conducted. Global maintenance costs for both PULSA pumps and PULSA SOLAR pumps over a long period can be limited to $ 0.50 (US) per person per year. The additional investment cost of a PULSA SOLAR pump, if written off over a period of 10 yr, amounts to $ 1.50 per person per year in a village of 200 persons. (See also W91-02288) (Rochester-PTT)

DESIGN AND MANAGEMENT OF RURAL WATER SUPPLY PROJECTS: LESSONS LEARNED FROM COMPARATIVE STUDY OF USAID PROJECTS IN BURKINA FASO AND TOGO.
Water and Sanitation for Health Project, Arlington, VA.
P. Roark.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 902-910, 2 ref.

Descriptors: *Benefits, *Burkina Faso, *Developing countries, *Political aspects, *Public policy, *Rural areas, *Togo, *Water supply, Governmental interrelations, Maintenance, Management planning, Public health, Sanitation, Social aspects, Water resources development, Wells.

The design and management of rural water supply projects in many developing countries require the active participation of four institutional entities: government, local communities, private sector entrepreneurs, and international donors. A comparative study of two United States Agency for International Development (USAID)-funded projects in Burkina Faso and Togo provides interesting conclusions on the roles that each of the entities can assume most efficiently. The projects were similar in that they installed more than 1700 wells in specific regions of the two countries and stressed community development and health education as a part of the total program. Their design and management approaches were, however, different and led to different results and conclusions. The Burkina Faso project was conducted separately from the national government; it had its own personnel (342) and vehicles, office, and other equipment. Most of the staff were temporary and their employment ended at the end of the project. In Togo, existing social and technical agencies were involved and the well drilling itself was conducted by a private firm hired through a competitive bidding process. The advantage of the Togo project is that project sustainability and replicability are entrenched within a permanent Togo government institution that will continue in the future. Balanced development requires projects to coordinate the individual components of water, sanitation, health, education, and community participation. More emphasis is needed in the latter three components to maximize the health benefits of water supply. Operations and maintenance of water systems continues to be a problem that will require more attention by project designers and managers in the future. (See also W91-02288) (Rochester-PTT)

KEY FACTORS IN TASTE AND ODOUR PROBLEMS FOR MUNICIPAL WATER WORKS USING SURFACE WATER SOURCES.
Waterloo Univ. (Ontario). Dept. of Civil Engineering.
E. A. McBean.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 881-891, 1990. 5 fig, 9 tab, 19 ref.

Descriptors: *Algae, *Aquatic bacteria, *Eutrophication, *Fungi, *Limiting nutrients, *Municipal water, *Odors, *Organoleptic properties, *Phytoplankton, *Taste, *Water pollution sources, *Water quality, *Water treatment, Diatoms, Lake Huron, Nitrates, Phosphorus, Silicates, Silicon.

Taste and odor problems of municipal water supplies can be grouped into two main categories: those associated with algae and other organisms naturally found in surface water, and those associated with industrial and municipal waste inputs to surface waters. This study considers taste and odor problems of natural origin. Planktonic algae are of importance in water supplies and water pollution, and fall into four classes: blue-green algae, green algae, diatoms, and pigmented flagellates. Fungi and bacteria associated with the decomposition of organic matter can also cause taste and odor problems. Primary environmental factors such as nutrient availability, sunlight and water temperature affect algal growth. Phosphorus is the most significant factor in blue-green algal blooms, while carbon and nitrogen are less likely to be limiting. Silicon, in the form of silicates, is essential to the growth of diatoms. Silicate depletion can limit diatom growth or cause a shift to other algae. A case study of five-year records at three locations from Lake Huron have indicated that: (1) the phytoplankton levels (primarily diatoms) are not of a level to create taste and odor problems; (2) when the total P levels are low, then P is limiting the growth of phytoplankton. When P concentrations increase, phytoplankton levels are not limited by P levels. In this situation, the phytoplankton intensities are responsive to levels of total Kjeldahl nitrogen, reactive silicate and nitrate. This finding is in agreement with other studies which indicate that with the high biomass of diatoms in the spring, silica concentration probably becomes a limiting factor in Lake Huron, leaving room for more eutrophic forms to develop later in the season. RELATING EMPIRICAL WATER QUALITY DIAGRAMS AND PLANKTON-DYNAMICAL MODELS: THE SAMPLE METHODOLOGY APPLIED TO A DRINKING WATER STORAGE RESERVOIR.
Rijksinstituut voor de Volksgezondheid, Utrecht (Netherlands).
T. Aldenberg, and J. S. Peters.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 893-911, 1990. 5 fig, 9 tab, 20 ref, 4 append.

Descriptors: *Drinking water, *Model studies, *Phytoplankton, *Sensitivity analysis, *Storage reservoirs, *Water quality, *Zooplankton, Chlorophyll, Irradiation, Limiting factors, Nutrients, Transparency, Water quality trends.

Relationships have been established betwee trends in empirical water quality diagrams an sensitivity of steady states of plankton-dynamica models to changes in input, such as nutrient loa and irradiance. A model with two trophic levels not likely to show input sensitivity to water qualit parameters like chlorophyll or transparency. Inpu responsiveness is carried over to the second troph ic level instead. To illustrate the methodology, th model is applied to data from a drinking wat storage reservoir near Amsterdam. The approac can be put into a more general setting. The limitin factor concept can be defined rigorously throug sensitivity analysis, which also seems the rig framework for monitoring indirect effects in gene al. The SAMPLE acronym (Sensitivity-Adde Models for the Prediction of Linkages in Ecosy tems) stresses the fact that, in order to monit these linkages (indirect effects), sensitivity modul could be a permanent and invaluable part of ec logical models. The linkages in fact then becon states themselves. (Author's abstract)

The water utility industry has been and is se ways to use computer technology to enhance ations and management. One of the more exc technologies to emerge in the last decade i expert system. An expert system is designe simulate the advice and knowledge that ex provide about a problem or domain. These lack of potential applications for expert sy within the water industry. Generic expert sys

owever, are not a viable alternative for water ilities at this time. Expert systems can be applied any decision-making process. The more time voted to the development of the expert system, e more it will mimic the expert. Therefore, ap-ying expert systems is site and situation-depend-t. The major cost associated with an expert stem is usually the labor needed for development d maintenance. Computer hardware and soft-re should be carefully chosen with this in mind. with any other technology, it is important to refully assess its usefulness and effectiveness fore considerable resources are committed and pended. The usefulness of expert systems to a rticular utility can probably best be determined that utility. (Mertz-PTT)

ural waters typically contain 2 to 10 mg/L olved organic carbon (DOC). A refractory, chromatographable fraction comprising 85 to percent of the DOC is often improperly re-ed to as 'humic acids'. Considerable interest in transformation of these refractory organics ng treatment processes was sparked by the overy that the chlorination of humic sub-ces could yield toxic trihalomethanes (THMs). e 1985, a preseparation technique has been eloped using pyrolysis/gas chromatography)/mass spectrometry (MS). This method ws the preparation of apparent molecular ght fractions. Extensive use of pyrolysis/GC/ to further characterize these fractions has led significant results concerning the varying re of DOC and thus an understanding of many cts of water treatment, such as the efficiency agulation processes, the wide variations in the M formation potential between waters of differ-origins, the competitive effects in adsorption or ation processes, and the fouling problems in brane processes. M ZERO TO 20 MGD IN TEN MONTHS.
Indianapolis Water Co., IN.
G. S. Lyons.
Public Works PUWOAH, Vol. 121, No. 10, p 92-93, September 1990. 2 fig.

Descriptors: *Project planning, *Upgrading, *Water conveyance, *Water supply development, *Water treatment facilities, Drought effects, Indiana, Pumps, Water distribution, Water pressure, Wells.

The Indianapolis Water Company experienced low pressures and inadequate domestic and fire flow in seven sections of their service area during the drought of 1988. Problems due to treatment and transmission were experienced in the extremities of the system in four separate pressure districts. The company engineering department developed an eight-item improvement plan with an estimated cost of $9 million, to be implemented within one year. Seven of the eight projects were completed by the summer on 1989, resulting in no complaints attributed to low pressure in the four previously troubled areas. In addition, work came in $1 million under budget. The seven completed projects, which included constructing new well fields and adding and improving pump stations, provided 20 million gallons/day additional production and/or pumping capacity. Having a continuous and competent short, middle, and long-range system planning program and owning the land needed for the projects in advance of the actual need for plant construction significantly helped expediate implementation of improvements. Maintaining a competent engineering organization and obtaining the authorization to specify and order necessary equipment also kept the project moving at its rapid rate. Careful selection of local consulting engineering firms to spread the work and close monitoring of costs on a weekly basis allowed for continuous work flow within budget. Adding bonus/penalty in-service date clauses to contract documents provided incentives to complete projects on time. (Mertz-PTT)

Controlling well pumps, storage tanks, and distribution system flow became more efficient and cost-effective when existing controls were upgraded with a computer in Atlantic Beach, North Carolina. Atlantic Beach is a small resort community on the North Carolina coast with a year-round population of 2000. The summer population climbs above 20,000 from May through September, with a peak of 50,000 on July 4th weekend. This wide population spread places unusual demands on the water supply system. The water supply comes from four wells, a fifth well is being added in 1990. The main problem with the existing control system was that lead well selection was based on the ground storage tank reaching its full level of 17 feet. Each time it did, another well was selected to be the lead well. However, this caused many short pump cycles in the off-season winter months. The lead well would pump for more than the recommended 12 hours, because lead well selection was based on tank level, not time. Economics dictated using existing equipment where possible. The wells' telemetering system could be used. Also, the water plant's existing pump control system could remain in place and act as the computer's backup. The only new equipment required was the computer, an interface relay panel (built on-site by the consultant), and customized software. The new program monitors the ground storage tank level, keeping the level between the high set point of 17 ft and a low set point of 12 feet. The computer selects a lead well pump to run when the ground storage tank is below 16 feet. It will run this pump for a total of 12 hours. The computer-based control system was operating in less than 8 weeks for under $15,000. The system has been on-line for over a year and functioning well. (Mertz-PTT)

LEIGH CREEK TOWN WATER SUPPLY--A HISTORY.
R. E. Reed.
Mines and Energy Review South Australia, No. 157, p 18-21, 1990. 3 fig, 7 ref.

Descriptors: *Desalination, *Leigh Creek, *Potable water, *Water supply, *Water supply development, Aroona Dam, Australia, Dams, Groundwater mining, Groundwater potential, Reverse osmosis, Saline groundwater, Salinity.

The township of Leigh Creek, 500 km north of Adelaide, Australia, was established progressively from 1941 to service the adjacent coalfields. Potable water was supplied initially from railway dams and natural catchments, but a more reliable source was required. The town was provided with water piped 48 km from Sliding Rock copper mine in 1944, but yields were low and the water was of poor quality. Aroona Dam was completed in 1954 to replace Sliding Rock, and this is still the main water source. By the mid-1970s, low water levels in Aroona Dam caused renewed interest in groundwater at Sliding Rock and areas closer to Leigh Creek. A drilling program was carried out in 1978, supplemented by further holes in 1981, and followed by a major program of 112 holes in 1982-83. Fifteen production wells resulted, with salinities ranging from 500 to 10,000 mg/L. These now supply up to 5.3 ML/day to a reverse osmosis desalination plant capable of producing 3.4 ML/day of potable water. (Author's abstract)

TOTAL TRIHALOMETHANE FORMATION DURING TARGETED AND CONVENTIONAL CHLORINATION OF SEAWATER FOR BIOFOULING CONTROL.
N. M. Ram, Y. G. Mussalli, and W. Chow.
Research Journal of the Water Pollution Control Federation JWPFA5, Vol. 62, No. 6, p 789-795, September/October 1990. 8 fig, 3 tab, 25 ref. EPRI Project RP 2300-2.

Descriptors: *Biofouling, *Chlorination, *Trihalomethanes, *Water pollution sources, *Water treatment, Condensers, Effluents, Electric powerplants, Path of pollutants, Powerplants, Seawater, Water quality control.

Microbiological fouling of condenser tube surfaces is a major contributor to poor condenser performance, which in turn reduces power plant availability and reliability. Biofouling has been controlled in the past by the chlorination of cooling waters, a method subject to increasingly stringent regulatory control in response to environmental and health concerns. Utilities are attempting to use chlorine more efficiently by utilizing targeted chlorination, a technique involving the application of a relatively low dose chlorine solution (1.0 mg/L) for short periods of time (5 min) twice per day to selected fractional areas of the inlet tubesheet of the condenser. The potential for total trihalomethane (TTHM) formation was compared using conventional versus targeted chlorination. Results indicated that targeted chlorination significantly decreased TTHM formation when compared to the conventional chlorination of cooling waters. Bromoform was the predominant THM formed in all cases, owing to the oxidation of naturally occurring bromide in seawater when chlorinated, with subsequent conversion to bromoform when reacted with organic precursors. Introduction of additional chlorine to all samples yielded considerable TTHMs after a 7-day incubation, highlighting the importance of limiting chlorine dosage in complying with discharge limitations. TOXICOLOGICAL RISK/BENEFIT-ASPECTS OF DRINKING WATER CHLORINATION AND

OF ALTERNATIVE DISINFECTION PROCEDURES.
Forschungsinstitut fuer Mikrobiologie und Hygiene, Bad Elster (German D.R.).
K. Strobel, and H. H. Dieter.
Zeitschrift fuer Wasser - und Abwasser Forschung ZWABAQ, Vol. 23, No. 4, p 152-162, August 1990. 9 tab, 156 ref.

Descriptors: *Chlorination, *Disinfection, *Drinking water, *Toxicity, *Water treatment, Byproducts, Carcinogens, Chlorinated hydrocarbons, Mutagens, Risk assessment, Water pollution sources, Water quality control.

Although drinking water chlorination represents one of the biggest successes in sanitation achieved in this century, an important disadvantage of the procedure is the formation of toxic and mutagenic or even carcinogenic chlorinated organic compounds. Such compounds can also be found after application of alternative disinfectants (chlorine dioxide, ozone, stabilized hydrogen peroxide), but probably to a lesser extent. Chlorination remains the best method of disinfection at present because of its superior disinfection capacity and permanent protection of the distribution system. The reduction of the amount of organic precursors can be achieved using appropriate technologies for the treatment of raw wastewater (filtration, flocculation, aerated reservoirs, slow and rapid filtration, treatment with ozone and activated carbon) and by optimal protection of water reservoirs. In many cases, these techniques will eliminate the need for chlorination. Testing for organic precursors of by-products from chemical disinfection in drinking water and establishing limits for carcinogenic/mutagenic substances in chemically disinfected water are recommended. In the long run, the protection of drinking water resources and the creation of water catchment areas seem to be the most effective and economic ways to keep the pollution of drinking water by disinfection products at a minimum level. (Author's abstract)

MODELING INACTIVATION OF GIARDIA LAMBLIA.
Environmental Protection Agency, Cincinnati, OH. Risk Reduction Engineering Lab.
R. M. Clark.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 837-853, 1990. 3 fig, 12 tab, 21 ref.

Descriptors: *Disinfection, *Giardia, *Mathematical equations, *Mathematical models, *Regulations, *Standards, *Water treatment, Bacteria, Chlorination, Chlorine, Hydrogen ion concentration, Kinetics, Model studies, Surface Water Treatment Rule, Temperature, Viruses.

Under the auspices of the Safe Drinking Water Act (SDWA) the US EPA has promulgated the Surface Water Treatment Rule (SWTR) requiring public water systems using surface water to provide minimum disinfection to control Giardia lamblia, enteric viruses, and bacteria. The C X t concept (concentration of disinfectant in mg/L times time in minutes) is used to establish the appropriate criteria for a surface system to achieve at least 99.9% inactivation of Giardia lamblia, and 99.99% inactivation for viruses. In the SWTR, an empirical equation was developed based on water temperature, pH, concentration of chlorine, and inactivation level, to predict required disinfection criteria (C X t values). This paper describes the development of an equation, based on Chick-Watson kinetics, that provides equivalent information but is theoretically more consistent. The equation can be used to predict C X t values for achieving 0.5 to 4 logs of inactivation, within temperature ranges of 0.5 to 5 C, chlorine concentrations up to 4 mg/L, and pH levels of 6 to 8. (Author's abstract)

FILTRATION/ADSORPTION MEDIA FOR BACTERIA AND TURBIDITY REMOVAL.
Malnad Coll. of Engineering, Hassan (India). Dept. of Civil Engineering.
S. Jayadev, and M. Chaudhuri.
Journal of Environmental Engineering (ASCE) JOEEDU, Vol. 116, No. 5, p 998-1000, 1990. 3 fig, 5 ref.

Descriptors: *Adsorption, *Bacteria, *Filtration, *Turbidity, *Water treatment, Alum, Developing countries, Domestic water, Escherichia coli, Viruses.

In recent studies on the development of low cost filtration/adsorption media for the removal of bacteria and turbidity from water, alum-treated Giridih bituminous coal (alum-GBC) and ferric hydroxide-impregnated lignite (Fe-lignite) ranked highest among the coal/lignite-based media. However, a significant fraction of the sorbed bacteria remained viable and eluted in a desorption study. This technical note presents the results of Escherichia coli sorption/inactivation and sorption-desorption studies, and a down-flow column test to assess the usefulness of incorporating silver into alum-GBC and Fe-lignite in improving their performance. The results presented, together with the data on enteric (polio and rota) virus removal by alum-treated Giridih bituminous coal, suggest the potential usefulness of silver incorporated alum-treated bituminous coal as a medium for domestic water filtration in rural areas of developing countries. Further work is underway to standardize the method of medium preparation and to test its performance using raw water (surface and ground) from different sources. (Lantz-PTT)

TECHNOLOGIES AND COSTS FOR THE TREATMENT OF MICROBIAL CONTAMINANTS IN POTABLE WATER SUPPLIES.
Pirnie (Malcolm), Inc., Paramus, NJ.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-175426. Price codes: A15 in paper copy, A01 in microfiche. October 1988. 315 p, 18 fig, 80 tab. EPA Contract 68-01-6989.

Descriptors: *Costs, *Drinking water, *Potable water, *Water treatment, Bacteria, Economic aspects, Giardia, Groundwater quality, Technology, Turbidity, Viruses, Water quality.

The best technologies taking costs into consideration, for inactivating or removing microbial contaminants from surface water and groundwater supplies of drinking water were examined. For municipal officials, engineers and others, the document provides a review of alternative technologies and their relative efficiency and cost, and addresses water treatment technologies that may be used by community and non-community water systems in removing turbidity, Giardia, viruses, and bacteria from water supplies. The US EPA is developing treatment regulations addressing these microbial concerns. A brief discussion of disinfection technologies and costs for groundwater supplies is also provided, since disinfection is the best available technology for groundwater systems to comply with coliform regulations. The information provided is intended to assist in reviewing available technologies for achieving the required reduction in turbidity and microorganisms. (Author's abstract)

GUIDANCE MANUAL FOR COMPLIANC WITH THE FILTRATION AND DISINFE TION REQUIREMENTS FOR PUBLIC WATE SYSTEMS USING SURFACE WATE SOURCES.
Pirnie (Malcolm), Inc., Paramus, NJ.
Available from the National Technical Informati Service, Springfield, VA 22161, as PB89-20704 Price codes: A16 in paper copy, A01 in microfich Draft Report, March 31, 1989. 361 p, 12 fig, 11 ta 169 ref, 15 append. EPA Contract 68-01-6989.

Descriptors: *Disinfection, *Filtration, *Manua *Standards, *Water quality, *Water suppl *Water treatment, Institutional constraints, Reg lations, Surface water, Water supply developme

This draft Guidance Manual compliments the p posed filtration and disinfection treatment requi ments for public water systems using surface wa sources (otherwise known as Surface Water Tre ment Requirements (SWTR)). The purpose of t manual is to provide guidance to the EPA regio offices, individual States, and affected utilities the implementation of the SWTR, and to h ensure that actions taken toward implementati are consistent. This manual is advisory in nat and is meant to supplement the criteria listed un the proposed SWTR. For example, the SWTR s treatment requirements which encompass a la range of source water conditions. The guida manual suggests design, operating and perfor ance criteria for specific surface water quality c ditions to provide the optimum protection public health through multiple barrier treatm These recommendations are presented as gui lines rather than an extension rule. They are fered to give the Primary Agency flexibility establishing the most appropriate treatment quirements for the waters within their jurisdicti In order to facilitate the use of this manual, it been structured to follow the framework of proposed SWTR as closely as possible. FINITE ELEMENT GROUNDWATER MODEL AS ESSENTIAL PLANNING TOOL: MICROBIOLOGICAL DENITRIFICATION OF A WELL FIELD AT BROICHHOF.
Lahmeyer International G.m.b.H., Frankfurt am Main (Germany, F.R.).
H. Lutkestratkotter, and W. Pelka.
IN: Groundwater Management: Quantity and Quality. Proceedings of the Symposium held at Benidorm, Spain, October 2-9, 1989. International Association of Hydrological Sciences, Washington, DC. 1989. p 359-368, 8 fig.

Descriptors: *Denitrification, *Finite element method, *Germany, *Groundwater management, *Hydrologic models, *Model studies, *Nonpoint pollution sources, *Water pollution sources, *Water quality management, *Water treatment, *Well fields, Aerobic treatment, Drinking water, Field tests, Flow system, Graphical methods, Groundwater movement, Hydraulic properties, Rehabilitation, Water resources management.

Increased nitrate content in groundwater caused by mineral-based fertilizers calls for newly developed denitrification measures and processes. To develop such processes, it is necessary to combine theoretical research, field tests, and engineering activities. A research project was undertaken in Germany on rehabilitation of aquifers by controlled denitrification and final underground aerobic treatment. The aim of the project was to determine all relevant operational parameters for large scale application in waterworks. Groundwater flow and hydraulic parameters were tested in some detail. Research in the aquifer meant a number of impacts on both the hydraulic and quality conditions of the aquifer. A finite element model with linear triangular elements was applied. The flow regime was analyzed under the assumption of various boundary conditions and used as a basis to design and to optimize test wells and infiltration galleries. During model calibration a high degree of accuracy was reached resulting in only very small deviations between simulated and historically observed water table values for all cases compared. To facilitate the interpretation and comparison of results from the various simulations, the model directly produces graphic output comprising inter alia contour lines and flow vectors. It is planned to extend the model to simulate the transport of constituents in addition to pure groundwater flow. It was found that the finite element model proved to be a valuable tool, since field work in a multi-use aquifer had to be coordinated with regular waterworks operation and other activities. COST SUPPLEMENT TO TECHNOLOGIES AND COSTS FOR THE REMOVAL OF MERCURY FROM POTABLE WATER SUPPLIES.
Environmental Protection Agency, Washington, DC. Criteria and Standards Div.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-192538. Price codes: A06 in paper copy, A01 in microfiche. January 1987. 109p, 7 fig, 24 tab, 3 append.

Descriptors: *Costs, *Economic aspects, *Heavy metals, *Mercury, *Potable water, *Water treatment, Activated carbon, Coagulation, Cost-benefit analysis, Filtration, Granular activated carbon, Lime, Reverse osmosis, Surface water, Water quality.

The cost estimates are a supplement to the cost section which appears in the December 30, 1984, report entitled, 'Technologies and Costs for the Removal of Mercury from Potable Water Supplies'. Because mercury is not commonly found in groundwaters, capital and operating costs for mercury removal technologies were only developed for surface water supplies. Cost estimates for the identified technologies have been developed based on information concerning waste disposal, capital costs and plant size. Costs were not developed for technologies identified as having future potential because additional testing and full-scale evaluations are necessary to determine design criteria and costs. The technologies for which updated costs were developed are: (1) coagulation/filtration, modified with powdered activated carbon for total mercury removal; (2) lime softening, modified for inorganic mercury removal; (3) granular activated carbon (GAC) for total mercury removal; (4) coagulation/filtration with activated carbon for total mercury removal (5) reverse osmosis for total mercury removal; (6) point-of-use treatment; (7) regionalization; and (8) alternate source. GAC was found to be the most economical treatment technology for new systems. (Lantz-PTT)
W91-02725

COST SUPPLEMENT TO TECHNOLOGIES AND COSTS FOR THE REMOVAL OF NITRATES AND NITRITES FROM POTABLE WATER SUPPLIES.
Environmental Protection Agency, Washington, DC. Criteria and Standards Div.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-192488. Price codes: A05 in paper copy, A01 in microfiche. First Draft. February 1987. 72p, 7 fig, 17 tab, 3 append.

Descriptors: *Costs, *Economic aspects, *Groundwater quality, *Nitrates, *Nitrites, *Potable water, *Water treatment, Chlorination, Cost-benefit analysis, Ion exchange, Reverse osmosis, Water quality, Wells.

The cost estimates are a supplement to the cost section which appears in the September 30, 1985, report entitled, 'Technologies and Costs for the Removal of Nitrates and Nitrites from Potable Water Supplies. Since nitrates and nitrites are generally found in groundwater supplies, capital and operating costs for all technologies were developed. Cost estimates for the technologies identified and were developed for the following technologies: (1) ion exchange; (2) breakpoint chlorination (nitrites only); (3) reverse osmosis; (4) point-of-use; (5) modifying existing wall systems; (6) regionalization; and (7) alternate sources. The most economical method of treatment for systems with capacities between 0.01 and 0.3 million gallons per day (mgd) is to modify the existing well systems. For plant design capacities > 0.3 mgd, breakpoint chlorination is the most economical treatment technology for nitrites, and modifying existing well systems is the most economical for nitrates. (Lantz-PTT)
W91-02726

COST SUPPLEMENT TO TECHNOLOGIES AND COSTS FOR THE REMOVAL OF CHROMIUM FROM POTABLE WATER SUPPLIES.
Environmental Protection Agency, Washington, DC. Criteria and Standards Div.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-192470. Price codes: A03 in paper copy, A01 in microfiche. First draft. February 1987. 131 p, 8 fig, 30 tab, 3 append.

Descriptors: *Chromium, *Costs, *Economic aspects, *Potable water, *Water treatment, Anion exchange, Coagulation, Cost-benefit analysis, Filtration, Heavy metals, Reverse osmosis, Water quality.

The cost estimates are a supplement to the cost section which appears in the January 31, 1985, report entitled 'Technologies and Costs for the Removal of Chromium from Potable Water Supplies'. Since chromium is generally found in surface water supplies, capital and operating costs for all technologies were developed. Cost estimates for the identified technologies were developed based on information concerning waste disposal, capital costs and plant size. Costs were not developed for technologies identified as having future potential because additional testing and full-scale evaluations were necessary to determine design criteria and costs. The technologies for which updated costs were developed include the following: (1) coagulation/filtration, modified for removal of chromium (VI); (2) coagulation/filtration, new for removal of total chromium; (3) anion exchange for removal of chromium (VI); (4) cation exchange for removal of chromium (III); (5) lime softening, modified for removal of chromium (III); (6) lime softening, new for removal of chromium (III); (7) two-bed ion exchange for removal of total chromium; (8) reverse osmosis for removal of total chromium; (9) point-of-use; (10) regionalization; and (11) alternate source. For chromium removal, the most economical treatment alternative was found to be anion exchange; and for total chromium removal, two-bed ion exchange was found to be the most economical. (Lantz-PTT)
W91-02727

COST SUPPLEMENT TO TECHNOLOGIES AND COSTS FOR THE REMOVAL OF SELENIUM FROM POTABLE WATER SUPPLIES.
Environmental Protection Agency, Washington, DC. Criteria and Standards Div.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-192496. Price codes: A07 in paper copy, A01 in microfiche. First draft. February 1987. 137 p, 7 fig, 30 tab, 3 append.

Descriptors: *Costs, *Economic aspects, *Potable water, *Selenium, *Water treatment, Activated alumina, Coagulation, Cost-benefit analysis, Filtration, Heavy metals, Lime, Reverse osmosis.

The cost estimates are a supplement to the cost section which appears in the November 18, 1985, report entitled, 'Technologies and Costs for the Removal of Selenium from Potable Water Supplies'. Because selenium is not commonly found in groundwater, capital and operating costs for seleni-

um removal technologies were only developed for surface water supplies. Cost estimates for the identified technologies were developed based on information concerning waste disposal, capital costs, and plant size. Costs were not developed for technologies identified as having future potential because additional testing and full-scale evaluations were necessary to determine design criteria and costs. The technologies for which updated costs were developed include: (1) coagulation/filtration, modified for Se (IV) removal; (2) coagulation/filtration, new for Se (IV) removal; (3) activated alumina for Se (IV) and Se (VI) removal; (4) lime softening, modified for Se (IV) removal; (5) lime softening, new for Se (IV) removal; (6) reverse osmosis; (7) point-of-use treatment; (8) regionalization; and (9) alternate source. For Se (IV) removal, activated alumina was the most economical treatment alternative for design capacities < 40 million gallons per day (mgd). For systems > 40 mgd, coagulation/filtration was the most economical. Reverse osmosis was found to be the most economical alternative for the removal of Se (VI) and total Se. (Lantz-PTT)
W91-02728

COST SUPPLEMENT TO REMOVAL OF CADMIUM FROM POTABLE WATER SUPPLIES.
Environmental Protection Agency, Washington, DC. Criteria and Standards Div.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-192462. Price codes: A07 in paper copy, A01 in microfiche. First draft. February 1987. 139p, 7 fig, 31 tab, 3 append.

Descriptors: *Cadmium, *Costs, *Potable water, *Water treatment, Coagulation, Corrosion control, Cost-benefit analysis, Economic aspects, Filtration, Heavy metals, Hydrogen ion concentration, Ion exchange, Lime, Reverse osmosis, Water quality.

The cost estimates presented a supplement to the cost section which appears in the April 1, 1985, report entitled 'Technologies and Costs for the Removal of Cadmium from Potable Water Supplies. Since cadmium is generally found in surface water supplies, capital and operating costs for all technologies were developed for surface waters. Cost estimates for the identified technologies have been developed based on information presented concerning waste disposal, capital costs and plant sizes. Costs were not developed for technologies identified as having future potential because additional testing and full-scale evaluations are necessary to determine design criteria and costs. The following cost estimates have been developed: (1) ion exchange; (2) coagulation/filtration, both modified and new; (3) lime softening, both modified and new; (4) reverse osmosis; (5) stabilization of corrosion waters; (6) pH adjustment; (7) corrosion inhibitors; (8) point-of-use; (9) regionalization; and (10) alternate source. The most economical method for treatment for systems with capacities of 0.1 million gallons per day and greater was found to be corrosion inhibitors. Of the cadmium removal technologies, ion exchange was found to be the most economical. (Lantz-PTT)
W91-02729

COST SUPPLEMENT TO TECHNOLOGIES AND COSTS FOR THE REMOVAL OF ASBESTOS FROM POTABLE WATER SUPPLIES.
Environmental Protection Agency, Washington, DC. Criteria and Standards Div.
Available from the National Technical Information Service, Springfield, VA 22161, as PB89-192447. Price codes: A06 in paper copy, A01 in microfiche. First draft. February 1987. 115p, 7 fig, 23 tab, 3 append.

Descriptors: *Asbestos, *Costs, *Economic aspects, *Potable water, *Water treatment, Coagulation, Cost-benefit analysis, Diatomaceous earth, Filtration, Inhibition, Surface water, Technology.

The cost estimates are a supplement to the cost section which appears in the February 5, 1986, report entitled, 'Technologies and Costs for the Removal of Asbestos from Potable Water Supplies'. Since asbestos is generally found in surface water supplies capital and operating costs for all technologies were developed for surface waters. Cost estimates for the identified technologies have been developed based on information presented concerning waste disposal, capital costs, and plant size. Costs were not developed for technologies identified as having future potential because additional testing and full-scale evaluations are necessary to determine design criteria and costs. The technologies for which updated costs were developed fall into two groups. This grouping was established in the Technologies and Costs document for the removal of asbestos. Group I technologies have been identified as the best generally available treatment methods for reducing asbestos, and include: 1) coagulation/filtration, modified; (2) direct filtration, modified; (3) direct filtration, new; (4) stabilization of aggressive waters; and (5) inhibitors. Group II are more expensive than Group I, and include: (1) coagulation/filtration; (2) filtration, diatomite; (3) regionalization; and (4) alternate source. Direct filtration was found to be the most economical of the removal technologies, below 1 million gallons per day (mgd) design capacity and above 10 mgd. Between these values, diatomite filtration was found to be the most economical. (Lantz-PTT)

EXPANDING THE ROLE FOR THE POU/POE INDUSTRY.
Environmental Protection Agency, Washington, DC. Office of Drinking Water.
M. B. Cook.
Environmental Geology and Water Sciences EGWSEI, Vol. 16, No. 2, p 133-134, 1990.

Descriptors: *Water quality, *Water quality control, *Water treatment, Chlorination, Marketing, Odor control, Organoleptic properties, Public health, Taste, Water quality standards.

The point-of-use/point-of-entry (POU/POE) industry, along with the bottled water industry, is growing rapidly and has the prospect for continuing high growth for many years into the future. The Environmental Protection Agency believes that POU/POE devices can meet a variety of needs: helping consumers deal with taste and odor problems associated with chlorine and other disinfectants in the water; and dealing with the contamination of private and small water system wells. POU/POE vendors need to enhance and protect their credibility, by ensuring that they know exactly what contaminants of concern exist and that their devices will actually remove such contaminants effectively, and by providing more technical training for its staff and operators. POU/POE vendors and utilities should support each others' roles, by discussing with each other how the industry might improve the quality of their sales techniques and marketing. The POU/POE industry would better serve public health by supporting the appropriate treatment of central water supplies to meet federal and state standards over the long run. (Fish-PTT)

Descriptors: *Activated carbon, *Adsorption kinetics, *Surfactants, *Water treatment, Adsorbents, Drinking water, Model testing, Nonionic surfactants, Organic pollutants, Phenols, Solutes, Water pollution.

Activated carbon adsorption is an effective process for the removal of organic micropollutants found in drinking water supplies. When two solutes are present in the solution with the adsorbent material, complex reactions will exist in the system. The adsorption characteristics of two solutes such as surfactants and phenols in micromolar range in water were determined in batch reactors, using powdered activated carbon as adsorbent. Phenol and equilibrium parameters were determined by use of Langmuir or Derylo-Jaroniec equations for a single adsorbate. In dilute mixture the adsorption is very strong with the carbon surface. For bisolute organic compound adsorption (anionic-nonionic surfactants, cationic-nonionic surfactant, or N-2-cationic surfactant mixture), experimental results were compared with two models from the literature. In all cases, the Derylo-Jaroniec model can not be conveniently calculated. Only the Jain-Snoeyink model gives relatively good concordance between calculated values and the experimental results. This model shows a part of the competitive sites for the two solutes and a part of the specific one for the compound which has the greater maximum adsorption capacity. It appears that an inhibition effect of a solute by another solute can exist on the specific sites when the coadsorbate is a relatively large molecule. For the evolution of the maximum capacity adsorption two models were tested: a concurrential equation and another which serves to calculate another parameter, characteristic of inhibition, no effect or promotion, on the specific adsorption sites. IMPACT OF NITROGEN ON THE ADSORPTIVE CAPACITY OF ACTIVATED CHARCOAL.
University of Petroleum and Minerals, Dhahran (Saudi Arabia). Dept. of Civil Engineering.
G. Nakhla, J. Qubaih, N. Abu-Zaid, and M. Abdulappa.
Environmental Technology (Letters) ETLEDB, Vol. 11, No. 8, p 731-738, 1990. 5 fig, 2 tab, 17 ref.

Descriptors: *Activated carbon, *Nitrogen, *Surfactants, *Wastewater treatment, *Water treatment, Adsorbents, Adsorption, Anaerobic conditions, Anoxic conditions, Granular activated carbon, Solutes.

Many researchers have demonstrated the successful treatment of water and wastewaters using surface active media, most commonly activated carbon due to its superior microbial attachment properties and its excellent adsorption characteristics. The standard static-bottle procedure, which involves adding a stock solution of adsorbate to different amounts of activated carbon and mixing until equilibrium is attained, does not accurately simulate anoxic conditions which may be prevalent in anaerobic granular activated carbon (GAC) reactors as well as GAC contactors of sufficient depth and biological activity to deplete the dis-

solved oxygen. The effect of nitrogen on adsorptive capacity of activated charcoal was investigated. Adsorption isotherms for phenol on activated charcoal at neutral pH and room temperature (23 C) were conducted using the standard bottle-point technique and a modified method which involves purging the solution with nitrogen to insure exclusion of oxygen. The observed differences in adsorptive capacities between the two techniques were statistically significant. Nitrogen was observed to reduce the capacity of activated charcoal by as much as 50%. DEGRADATION OF BLUE GREEN ALGA, MICROCYSTIS AERUGINOSA BY FLAGELLATA, MONAS GUTTULA.
Ibaraki Prefecture Inst. of Public Health, Mito (Japan).
N. Sugiura, Y. Inamori, R. Sudo, T. Ouchiyama, and Y. Miyoshi.
Environmental Technology (Letters) ETLEDB, Vol. 11, No. 8, p 739-746, 1990. 7 fig, 25 ref.

Descriptors: *Algal control, *Biodegradation, *Biological wastewater treatment, *Cyanophyta, *Flagellates, *Microcystis, *Water treatment, Biological oxidation, Growth rates, Japan, Saturation index.

The occurrence of blue-green alga, Microcystis, in many eutrophic lakes and reservoirs is responsible for unpleasant odor, fish kills due to sharp decrease of oxygen, and death of wild birds and cattle due to ingestion of the toxin produced by some strains. Microcystis causes deterioration of coagulation, flocculation, filter-clogging, and acceleration of organic chlorides-formation in conventional water treatment processes. Characteristics of degradation of Microcystis aeruginosa by the small flagellata Mastigophora-Monas guttula were examined. Monoxenic M. guttula was isolated from sewage in the biological oxidation facility in the Kasumigaura Water Works, Japan. It was found that M. guttula could efficiently degrade viable algal cells in a short time. The removal of the cells by M. guttula was 90% at 48 hours cultivation. The specific growth rate and generation time of M. guttula were 4.1/day and 4.0 hours, respectively, while maximum specific growth rate and saturation coefficient of the microbe were 4.4/day and 2.4 mg/L with the Lineweaver-Burk equation. It was concluded that M. guttula could effectively utilize M. aeruginosa as a food for its strong affinity and reactivity. (Author's abstract)

LARGE-SCALE BIOLOGICAL NITRATE AND AMMONIA REMOVAL.
Anjou Recherche, Maisons-Laffitte (France).
F. Rogalla, P. Ravarini, G. De Larminat, and J. Couttelle.
Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 4, No. 4, p 319-329, August 1990. 10 fig, 2 tab, 50 ref.

Descriptors: *Ammonia removal, *Biological treatment, *Drinking water, *Nitrates, *Water treatment, Aeration, Bacteria, Costs, Denitrification, Disinfection, Filtration, France.

In order to treat water containing nitrogen in excess of the European Drinking Water Guidelines an innovative, large scale biological, nitrogen-removal process has been used. After extensive pilot scale testing and a first full scale (80 cu m/h) demonstration, a 400 cu m/h installation, serving about 50,000 people, was built at Guernes-Dennemont, near Paris. The raw water source is a combination of percolation from agricultural plains and river bank infiltration, and contains both nitrate and ammonia. The plant consists of two fixed-bed biological reactors in series. An anoxic filter, using ethanol as a carbon source for heterotrophic bacteria, removes nitrates at filtration rates up to 10 m/h. The denitrified water is then polished on an aerated two layer filter, packed with activated carbon and sand. Excess carbon from the first stage, together with reduced nitrogen (ammonia and nitrates) is oxidized at this stage before ozonation of the water. A specific dosing method for biodegradable carbon was developed to monitor the efficiency of the post treatment. Special attention was paid to: (1) nitrate control through improved backwash, and (2) reducing the potential for bacterial contamination and after-growth in the distribution network. SECONDARY DISINFECTION OF SERVICE RESERVOIRS.
Yorkshire Water Authority (England). Western Div.
T. M. Pearson.
Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 4, No. 4, p 341-349, August 1990. 4 fig, 4 tab, 6 ref.

Descriptors: *Disinfection, *Secondary treatment, *Water quality, *Water quality control, *Water treatment, Bacteria, Case studies, Chemical treatment, Chlorination, Cost-benefit analysis, Hypochlorite, Potable water, Reservoirs, Ultraviolet radiation.

In order to comply with the European Community Directive on the quality of water intended for human consumption, which was embodied in the 1989 Water Act, a number of problems need to be addressed. One such problem is to identify a reliable method of secondary disinfection for service reservoirs which have a history of bacteriological failures. This paper considers the advantages and disadvantages of ultraviolet (UV) and chemical disinfection techniques (both hypochlorite dosing and on site generation of chlorine), together with the basic design features, and presents a case study examining capital and revenue costs. The collated information suggests that UV disinfection is a cost-effective secondary disinfection technique. This suggestion is supported not only by the cost benefits but also by the ease of operation, improved monitoring and control, and elimination of water quality problems associated with chemical techniques. EVOLUTION OF AN OZONE PROCESS AT LITTLETON WATER-TREATMENT WORKS.
Bristol Waterworks Co. (England).
D. J. Smith.
Journal of the Institution of Water and Environmental Management JIWMEZ, Vol. 4, No. 4, p 361-370, August 1990. 6 fig, 1 tab, 10 ref.

Descriptors: *Disinfection, *Drinking water, *Ozonation, *Ozone, *Water treatment, Biological treatment, Case studies, Costs, England, Granular activated carbon, Odor control, Organoleptic properties, Potable water, Taste.

Ozone is increasingly being considered as a means for improving the organoleptic quality of lowland surface waters, often in conjunction with granular activated carbon. The experiences of Bristol Water, who have recently introduced this process at Littleton water-treatment works to resolve long standing taste and odor problems, are described in this paper. The results of the pilot plant studies used to assess the effectiveness of the biological process promoted by ozone are reviewed. Performance requirements specified in the contract for the full scale plant are then outlined, together with a description of the civil works and equipment. Pilot plant studies demonstrated the effectiveness of ozone for disinfection, and that they did not produce unpleasant tastes and odors. Although the chemical revenue costs for ozone and superchlorination were similar, the capital costs of ozone installation were greater. The water quality benefits and operational effectiveness and costs of the ozone process will be evaluated over a 12-month period. (Lantz-PTT)

ANALYTICAL SOLUTION FOR ONE-DIMENSIONAL TRANSPORT IN HETEROGENEOUS POROUS MEDIA.
California Univ., Riverside. Dept. of Soil and Environmental Sciences.
S. R. Yates.
Water Resources Research WRERAQ, Vol. 26, No. 10, p 2331-2338, October 1990. 5 fig, 1 tab, 22 ref, append.

Descriptors: *Dispersion, *Groundwater movement, *Heterogeneity, *Hydrodynamics, *Porous media, *Solute transport, Aquifer characteristics, Aquifers, Diffusion, Dispersion coefficient, Estimating, Flow velocity, Mathematical analysis, Parameter estimation, Scaling.

An analytical solution for describing the transport of dissolved substances in heterogeneous porous media with a distance-dependent dispersion relationship can be used to characterize differences in the transport process relative to the classical convection-dispersion equation, which assumes that the hydrodynamic dispersion in the porous medium remains constant. The form of the hydrodynamic dispersion function used in the analytical solution $D(x)$ = distance-dependent dispersivity x average pore water velocity + diffusion. For models which differ only in how the dispersion function is expressed, erroneous model parameters may result from parameter estimation techniques which assume a constant hydrodynamic dispersion coefficient if the porous medium is more accurately characterized by a distance-dependent dispersion relationship. For such situations, the proposed model could be used to provide an alternate means for obtaining these parameters. The analytical solution should be useful for verifying the numerical accuracy of more comprehensive finite difference and finite element solutions to the transport equations as well as for investigating some aspects of the scale-dependent transport process. Using scale-dependent dispersion may provide an alternative means for obtaining aquifer parameters for situations where the dispersion coefficient is not spatially constant. (Brunone-PTT)

In situ bioreclamation is a promising new technique for enhancing the cleanup rate of aquifers contaminated with organic pollutants, and involves injecting the materials necessary to increase the microbiological activity in the subsurface. A methodology involving laboratory-column experiments

and computer modeling was utilized to investigate the formation of denitrifying biologically active zones (BAZs) in a porous medium, when a limiting electron acceptor NO3(-) is injected along the flow path. Laboratory experiments conducted in a unique one-dimensional porous-medium column demonstrated the relationship between lateral injection of NO3(-) and the location and extent of BAZs when acetate was present as the sole carbon source. The phenomena of BAZ formation and the utilization of limiting and non-limiting substrates were expressed quantitatively in a computer model that coupled principles of one-dimensional solute transport and steady-state biofilm kinetics. A new, highly efficient solution algorithm was developed to solve directly for the steady-state profiles of the limiting substrate and biofilm mass, as well as for the non-limiting substrate. The predictive ability of the model was verified by successful simulation of particular laboratory experiments using independently determined kinetic parameters for acetate. Research results indicate that injection of limiting substrate along the groundwater flow path is a viable means of establishing spatially distributed BAZs for enhanced in situ bioreclamation. Halogenated organic compounds are widely used as industrial solvents, dry cleaning solvents, metal degreasing agents, and pesticides. In situ bioreclamation is a promising approach to clean up aquifers contaminated with these compounds. When the compound is present in a very low concentration that is insufficient to meet the minimum energy requirements needed to maintain a steady-state biomass, the compound may be degraded by a secondary utilization mechanism. Laboratory experiments and numerical modeling were conducted to evaluate the secondary utilization of eight trace-concentration halogenated solvents in a denitrifying biologically active zone (BAZ) induced by nitrate injection into an acetate-fed porous-medium column. Results of column experiments indicated that carbon tetrachloride was removed most completely by the denitrifying BAZ, while bromoform, dibromoethane, tetrachlorethane, trichloroethene, 1,2-dichlorobenzene and 1,3-dichlorobenzene were removed, but to lesser degrees. 1,1,1-trichloroethane removal was slight. Compounds were removed to higher degrees when the BAZ contact time was increased. The steady-state, one-dimensional solute transport equation was solved using an iterative finite difference scheme and by employing a quasilinearization technique for the biofilm reaction term. The model solved directly for the steady-state profiles of secondary substrates. One set of experimental results was used to obtain best-fit values of kinetic parameters which were then used to predict the removal at different liquid flow velocities. The model predictions correctly described all experimental trends: removal of the halogenated compounds only in the BAZ, greater removal with increased BAZ contact time, and reduced specific removal rates caused by diffusion limitation in the biofilm. USE OF THE INDEX OF BIOTIC INTEGRITY TO ASSESS THE IMPACT OF LAND MANAGEMENT ACTIVITIES ON LOW ORDER STREAMS IN NORTHERN IDAHO.
Idaho Univ., Moscow. Dept. of Fish and Wildlife.
D. H. Bennett, and T. R. Fisher.
Available from National Technical Information Service, Springfield, VA 22161 as PB90-240052/AS. Price codes: A05 in paper copy, A01 in microfiche. Idaho Water Resources Research Institute, Moscow, Completion Report, October 1989. 79p, 16 tab, 11 fig, 31 ref, 10 append. USGS Contract no. 14-08-0001-G1419. USGS Project No. G1419-06.

Descriptors: *Bioindicators, *Idaho, *Index of biotic integrity, *Land management, *Land use, Fish, Stream biota, Stream fisheries, Stream profiles, Streams, Water quality.

The Index of Biotic Integrity (IBI) was adapted to the faunal characteristics of northern Idaho headwaters streams. Stream biota was sampled from June 1987 through September 1987. The original Index of Biotic Integrity, as developed for midwestern U.S. streams, was unsuitable for use in northern Idaho. Only four of the 12 metrics included in the original IBI reflected changes in the biotic integrity of northern Idaho streams. The original IBI, although significantly correlated with measures of stream quality, was too insensitive and classified lower quality streams as being in 'good to excellent' health. The original IBI was modified to contain eight metrics to reflect the health of the fish, amphibian, and aquatic macroinvertebrate communities. Also, expectation criteria of three metrics were adjusted for relative stream size. Our modified IBI seems to assess the health of northern Idaho headwater streams adequately. The modified IBI detected changes in stream health, as index scores were significantly correlated with road density and percent harvest of the drainages. Also, the modified IBI was more highly correlated with measures of impact and less significantly with measures of stream size than Shannon diversity of fishes by biomass of numbers, the Index of Well Being, Brillouin diversity of both fishes and aquatic macroinvertebrates. The modified Index of Biotic Integrity offers managers a technique to evaluate stream health with limited vertebrate and invertebrate sampling. Because the index was developed from data collected in northern Idaho streams with generally nonerosive rock types, it is not known how well this index would classify stream health in other regions of Idaho or other streams in the Pacific Northwest. AGRICULTURAL PESTICIDES AND GROUNDWATER IN NORTH CAROLINA: IDENTIFICATION OF THE MOST VULNERABLE AREAS.
North Carolina Water Resources Research Inst., Raleigh.
D. H. Moreau, and L. E. Danielson.
Available from National Technical Information Service, Springfield, VA 22161 as PB90-235359/AS. Price codes: A03 in paper copy, A01 in microfiche. North Carolina Water Resources Research Institute Report No. 252, May 1990. 31p, 12 fig, 6 tab, 11 ref, append.

Descriptors: *Agricultural chemicals, *Groundwater, *Groundwater pollution, *Monitoring, *North Carolina, *Pesticides, *Water pollution control, *Water pollution sources, Cost efficiency, Design criteria.

This report describes the methods and findings of research aimed at targeting areas in North Carolina where groundwater is vulnerable to contamination by agricultural pesticides. Areas that are most likely to be contaminated are identified by combining county-level estimates of pesticide use with indices of groundwater vulnerability. Results reported are intended as guides for more detailed research activities and for design of monitoring programs such as the one proposed by the North Carolina Interagency Working Committee on Groundwater Monitoring. The report presents results of research using the methods and criteria suggested. Estimates of quantities and spatial patterns of use are reported for the most heavily used pesticides that have the potential to leach into groundwater. Counties in North Carolina having the highest potential for groundwater contamination are identified. It is recommended that primary data on the sale and use of pesticides in North Carolina should be collected; that groundwater sampling should be implemented with a sustained funding base; and that indicators of vulnerability presented should be refined to pinpoint priority sites for monitoring. Several options for cost-effective information gathering about pesticide use in the state is suggested. (USGS)

PROBLEMS OF MAINTENANCE OF WATER QUALITY IN ARID AND SEMI-ARID REGIONS OF WEST AFRICA.
Ghana Univ., Legon. Dept. of Botany.
C. M. Amoah.
IN: The State-of-the-Art of Hydrology and Hydrogeology in the Arid and Semi-Arid Areas of Africa. Proceedings of the Sahel Forum, Ouagadougou, Burkina Faso, 18-23 February 1989. International Water Resources Association, Urbana, Illinois. 1990. p 722-735, 3 fig, 4 tab, 13 ref.

Descriptors: *Africa, *Developing countries, *Sahel, *Sudan, *Water pollution control, *Water pollution sources, *Water quality management, Agriculture, Arid lands, Drinking water, Education, Human diseases, Path of pollutants, Potable water, Semiarid lands, Social aspects.

The ecological problems of the Sahelian and Sudanian zone (SSZ) of West Africa have received considerable attention. In the arid and semi-arid regions of Africa, as in most other places, most water bodies are put to multiple uses. Fresh water is used for drinking, for livestock, in agriculture, transport, power generation, irrigation, industry, and recreation. The great demand on a limited water supply leads to various forms of degradation. Possible causes of contamination were examined and mitigating measures considered. The physical, social, and economic problems of maintaining water quality were examined. Specific recommendations made are as follows: (1) inhabitants should be educated about some of the human habits that lead to water pollution, such as throwing used wash water back into rivers; (2) bathing should be discouraged in drinking water sources; (3) water for human consumption should be separated from that used for livestock; (4) people infected with guinea-worm and bilharzia should be educated not to enter the water; (5) water should be filtered and boiled before drinking to kill disease-causing organisms; (6) water-borne disease prevention should be considered when expanding water supplies; and (7) government housing policy should embody a supply of good drinking water. PREDICTION ON EUTROPHICATION OF RESERVOIR YUQIAO.
Tianjin Inst. of Environmental Protection and Sciences (China).
X. Zhu, and R. Hou.
Ergebnisse der Limnologie ERLIA6, Vol. 33, No. 3, p 783-792, 1990. 5 fig, 4 tab, 7 ref.

Descriptors: *Erosion control, *Eutrophication, *Limnology, *Model studies, *Nutrients, *Reservoir operation, *Reservoirs, *Soil erosion, *Stream erosion, *Water pollution control, *Water quality management, *Water quality trends, Agricultural practices, Agricultural runoff, China, Fertilizers, Nitrogen, Nonpoint pollution sources, Pesticides, Phosphorus, Yuqiao Reservoir.

The impact of P and N inputs from nonpoint sources of agricultural runoff on the eutrophication of Yuqiao Reservoir in China was investigated. The magnitude of nutrient input from the 2060 sq km drainage area of the reservoir was evaluated, based on the synchronous measure of water quality and quantity. Loading rates for N and P to the reservoir surface were 4.31 and 0.79 g/sq m/yr, respectively. The future trophic state of the reservoir under changed hydrologic conditions, i.e., after a project to divert water from the Luan River into the Tianjin, is predicted by the nutrient loading-eutrophication response model (the Dillon Model). The results indicate that P loading must be reduced by about 65% in the Yuqiao Reservoir for it to change from eutrophic to mesotrophic. Management strategies for maintaining water quality of the reservoir include: (1) contour farming to reduce erosion potential; (2) leaving buffer strips of trees and shrubs along streams to reduce soil erosion; (3) grass seeding or other vegetation planting to stabilize areas of stream and reservoir banks to reduce soil-particle flushing and erosion; (4) use of culverts and other engineering structures to control water flow and thereby reduce erosion; (5) nutrient management practices, including fertilizer formulation, application rate, application techniques, and timing of application; and (6) pesticide management practices, including application methodology, timing, and rate of application. Descriptors: *Czechoslovakia, *Drinking water, *Sance Reservoir, *Water quality, Bacteria, Industrial wastewater, Nitrates, Ostravice River, Phosphates, Pollution index, Recreation, Water pollution sources.

The Sance Reservoir was built in 1969 as a drinking water supply from the Ostravice River, Czechoslovakia. Before dam construction was begun, the water quality of the reservoir was predicted from a hydrobiological investigation of the territory. These water quality investigations were conducted from 1972 to 1976, and again from 1980 to 1984. Tributaries of the reservoir were found to have maintained excellent water quality since 1954. Only dissolved matter and bacterial counts showed a small increase. The Sance Reservoir has had very good water quality, in agreement with the predictions (oligotrophy, oligo-betamesosaprobity). Only bacterial counts, nitrates, phosphates, and the saprobic index have shown a slight increase. In the future, only two dangers appear to exist: an increase in air pollution from a nearby industrial agglomeration, and an increase in water pollution as a result of recreation in the drainage area. The reservoir itself does not contribute to the deterioration of the water quality in the Ostravice River below the dam. (Sand-PTT)

A former sewage lagoon has been turned into the Twin Lake Recreation Area, a 60 acre tract within the Columbia, Missouri city limits, that includes a 6-acre swimming lake with a sand beach and a 20-acre L-shaped lake where nonmotorized craft can take advantage of prevailing winds. The lakes were reclaimed from an abandoned sewage lagoon in the early 1980s. Sludge was removed after draining the lagoon. The sludge was evenly spread under the proposed parking area. To assure minimal environmental impact, the sludge was covered with 12-18 inches of clay soil that had also been removed from the lagoon bottom. As an extra precaution, the site grading was designed to separate the watershed areas, thus eliminating any chance of sewage pollution entering the lake sites. Fish problems in the lake were controlled by rotenone applications. Copper complex based products have been used to control algae. A floating spray fountain will be added to the swimming lake for additional algae control. By introducing additional oxygen to the water, some of the nutrients present should be oxidized and made unavailable to the algae. (Mertz-PTT)
